

TIM HARTNELL'S **GIANT** BOOK OF COMPUTER GAMES

Program listings are compatible with MICROSOFT BASIC and will run on nearly all microcomputers, including BBC, VIC 20,* ORIC, APPLE II and APPLE IIe, COMMODORE 64, DRAGON 32, TANDY COLOR COMPUTER, IBM PC, LASER, TRS-80, PET, MZ80K and SPECTRUM.*

Many programs demand extra memory on the VIC 20. String-handling needs adapting to run the programs on the SPECTRUM.

Tim Hartnell founded both the magazine *ZX Computing* and the National ZX Users' Club. He is the author of more than thirty books on microcomputers, including *Tim Hartnell's Giant Book of Spectrum Games* (Fontana, 1983).

INTRODUCTION

Once upon a time it was not easy to write and play games with computers. Back in the dim, dark past, it could cost you \$80 to \$100 an hour just to rent access to a time-shared mainframe via a terminal. And the only output you had was on the printout of a noisy, hard to read teleprinter. Think what those restrictions would have done to your current pattern of spending hours lovingly debugging, and improving, your latest masterpiece.

We, fortunately, do not have to suffer such medieval conditions. The luxury of having a computer of your own, driving a TV screen, with unrestricted access to the machine, allows you to work for as long as you like creating games and other programs.

In this book, you'll find a collection of my favorite computer games. I hope some of them will soon be up and running on your computer, and will be stored with your own favorite programs. They're sure to provide you with a lot of fun in the weeks ahead.

I've tried to produce a set of games which will provide varied entertainment, to cater for your game interests, whatever they may be. As you'll see by glancing through this book, the games range from 'classic' board games like CHESS and REVERSI/OTHELLO, through just-for-fun simulations like the wacky MISTRESS OF XENOPHOBIA, to the demanding ADVENTURE programs STRONGHOLD OF THE DWARVEN LORDS and THE BANNOCHBURN LEGACY. There are more than 40 games in this book, which I wrote to ensure your computer never gets the chance to voice the complaint -- "I've got nothing to do" -- again.

I've deliberately written the book so that it is 'open-ended'. That is, in contrast to many other

collections of games programs on the market, I've assumed you'll want to adapt and improve the programs once you get them up and running. Therefore, with many of them I've included program breakdowns, some line by line, so you know what each section of code is doing. As well, the introduction to each section discusses a bit about the philosophy of writing games of that type, has a word or two to say about the basic algorithms which you can use to create games of that sort yourself, and generally aims to give you a solid background against which you can expand and develop your own games-writing skills.

Near the back of the book you'll even find a section devoted entirely to games ideas which you can convert into computer games.

Getting the programs running

I deliberately wrote the programs in this book in the most general version of BASIC I could. Therefore, you'll find no PEEKs and POKEs, no use of graphic character sets and no use of such commands as SOUND or PLAY. I've assumed you have access to READ and DATA, and that your screen is around 32 to 40 characters wide (and you'll find, if you have a computer like the VIC-20 with a screen which is not that wide, it is very easy to adapt the program output to fit, as many of the games only use the width of a playing board, say 12 characters). Standard string-handling commands (such as LEFT\$, RIGHT\$ and MID\$) are used, and these will need to be converted to the Sinclair 'string-slicing' mechanism if you have a computer such as the T/S 2000 or the Spectrum. This is not difficult to do, and I've kept even string-handling to a minimum in these programs so that the majority of programs should run on your system just by being typed in directly.

Of course, you'll probably have to play with the display a little, in order to make it as effective as possible. I expect, by the way, that you'll modify and adapt the programs to make the most of your system, adding sound and color, plus your own system's graphics, wherever you can.

Many of the programs reprint the board, or playing field, after each turn. For simplicity, I've preceded these 'reprints' with a CLS command to clear the screen. Some systems demand a command of the PRINT "CLR" type, so I'll expect you to make that replacement whenever you come to it. More importantly, you'll find that after the screen has been cleared at the start of the game, the output of the program can be made much more effective by replacing the CLS with a 'home' command, so that the program reprints 'on top of itself' each time round. This gives the impression in a program like ROBOT MINEFIELD for example, that the robots are moving. The same can be seen in the board games. Actually having the pieces move on the board is highly effective, and adds much to your enjoyment when running the programs.

Therefore, if your system has a means of resetting the cursor to the top of the screen without clearing it first (such as PRINT AT 0,0 or PRINT @ 0 or LOCATE 1,1 or the like) make sure you put this in the place of the CLS at the start of the reprint section.

These programs were written on an IBM PC*. On this computer, if I want to generate random integers in the range, say, 1 to 10, I use a command of the type $A = \text{INT}(\text{RND} * 10) + 1$. You'll find this format is used throughout the book. If your system does not accept this, you may have to substitute either $A = \text{RND}(10)$ or $A = \text{INT}(\text{RND}(0) * 10) + 1$ or $A = \text{INT}(\text{RND}(1) * 10) + 1$ (and you may well need to precede

this with LET). You probably know exactly how to do it right now, but if you're not sure, look up RND or 'random numbers' in your system's manual.

The computer on which I developed the programs always gives the same sequence of random numbers each time the program is run. As numbers which are more or less genuinely randomly distributed are needed in many programs, I've seeded the random number generator in each case by one of two methods.

I've either used INKEY\$ to hold the program in a loop, incrementing a variable as I do so, until a key is pressed, and then use that variable to seed the random number generator (as in RANDOMIZE N) or have taken the seconds part of the built-in clock on my computer as the seed (which gives rise to that rather terrifying-looking line RANDOMIZE VAL (RIGHT\$(TIME\$,2)) in many of the programs).

If your computer does not produce the same numbers in the same sequence every time you run the program, drop these lines altogether. Alternatively, just use RANDOMIZE (or RAND) without a following number, if your system accepts that. Again, your manual will tell you what to do. If you're not sure what to do, and your computer will not accept the long line including TIME\$, then just leave it out altogether. The program will function perfectly well without it.

Although much of the output within quote marks in PRINT statements is in lower-case, all programs (with the exception of the Chess one, which needs lower-case letters to signify the human's pieces) expect input in upper case letters. If your system does not have lower case letters, simply put the material in PRINT statements in upper case. It's been put in lower-case just because I think it looks better, but it has nothing to do with the actual running of the program.

You'll probably find, in fact, that when you get to entering the programs you'll automatically make the small changes needed to accomodate the special features of your system. I've included the above notes in the book just to make sure you can get the programs up and running as quickly as possible. However, you may well find you don't need them at all. So don't be intimidated by the length of this initial section of the book.

The majority of the programs in this book will fit well within 8K. THE BANNOCHBURN LEGACY is the exception, which demands nearly 17K on my system. CHESS occupies 8K, with the shorter programs generally under 4K. If you have trouble getting a program into your system because of shortage of memory, cut out the REM statements (the majority of GOSUB and GOTO calls do not reference the leading REM, but go to the actual routine itself which follows the identifying REM), and shorten the PRINT statements. It is impossible to predict exactly how much memory the programs will take on your system, because of the different ways memory is organised, and the working space the program requires differs from system to system.

To maximise the length of program you can get into your machine (and to keep program entry time down to a minimum) few of the programs include instructions. These are in the text. However, if you have the memory (and the inclination) you can easily add a "Do you want instructions" line as part of the initialisation subroutine, and then include a shortened form of the instructions from the text in your program.

I've followed structured programming techniques in all programs which lent themselves to that approach. This is explained in the material supporting the

Chess program. You may well find, as I did when I actually decided to put all the advice I'd read in books and articles into action, that working in a 'top down' manner made writing and modifying programs a much simpler, and more precise, activity than it had been before. As a bonus, it is much easier to get a program up and running when it's written this way. Most importantly, you can get to the fun parts -- actually running the thing -- much more quickly.

Many programs include a delay loop. As the actual delay produced will depend on your system, you should adjust these dummy loops (which are generally held in subroutines at the very end of the program) so that the screen display is as effective as possible.

Finally, a word about variables. In several cases complete words (such as SCORE) have been used as variable names. However, only the first two letters of the name are significant. If your system only accepts two-letter variable names, enter just the first two letters (such as SC in our example). Even if your system only recognizes the first two letters of a variable name, you should include the name in full if your system will accept it. You will find that it will be easier to understand what is happening within a program if you do this.

I think we should get to the fun parts immediately.

Good game-playing,

Tim Hartnell

May 1983

Board Games

Board Games

Some games could not have existed without computers.

Think of the whole range of Space Intruder types of games and the Pacperson ones. These could have not come into being before the computer - using a TV-like screen for output - was developed. Many other games, of course, predate the computer by thousands of years. However, more and more of these traditional games have now been computerised, with board games being as popular with computer games players as they were with players in precomputer days.

In this section of the book, we have a generous crop of board games:

- * CHESS
- * GOMOKU
- * FOUR IN A ROW
- * CHECKERS
- * SHOGUN (HASAMI SHOGI)
- * AWARI
- * KNIGHTSBRIDGE
- * REVERSI (OTHELLO)

We'll start this section of the book with a discussion on how board games can be easily modified to make it possible for a computer to handle them. Apart from Awari, the ideas we'll discuss in the next few pages have been applied for every board game in this section of the book.

There is a common thread which holds together all the programs in this section of the book, a thread which you can also use to help you develop programs to play your favorite board games.

Look first at this diagram. It shows a checkerboard numbered to make it easy for the computer to handle.

	1	2	3	4	5	6	7	8
8	81	82	83	84	85	86	87	88
7	71	72	73	74	75	76	77	78
6	61	62	63	64	65	66	67	68
5	51	52	53	54	55	56	57	58
4	41	42	43	44	45	46	47	48
3	31	32	33	34	35	36	37	
2	21	22	23	24	25	26	27	28
1	11	12	13	14	15	16	17	18

You can indicate any square on the board by referring to the number along the left hand side,

(such as 3), then the number along the top (such as 4). In this case, the lines numbered 3 (along the left hand side) and the line numbered 4 (along the top) meet at the square numbered 34. If you wish to move a piece, you can do so by entering the number of the square you're moving from (such as 55), then the number you're moving to (such as 66) and the computer can understand exactly what you're doing. There is no need to change the numbers entered by the human player into another set in order to allow the computer to interpret them.

That is the first 'secret' of writing board games so your computer can play them. The second is that a board numbered in this way has another great advantage over one which is simply numbered from one to 64 in order. When you move a piece in any direction on this board -- no matter where you start -- the difference between the squares is the same.

I'll try to expand on that somewhat cryptic statement. If you move one square up and to the right -- like the move of a piece in checkers -- you will move from, say, 24 to 35; or from 53 to 64; or from 71 to 82. But notice that no matter where you are on the board, the difference between your starting and ending squares is always 11. If you move diagonally up to the left, you'll move from, say, 26 to 35 (plus 9), or 66 to 75 (also plus 9) or from 22 to 31 (plus 9 again).

This predictability makes it relatively simple to create a board which the computer can handle.

How the computer plays

Imagine the computer has a checkers piece on the square numbered 24. It could be programmed to check each square on the board, and every time it found one of its own pieces, could check if there was a human piece on the square numbered the same as its

piece (that is, 24 in this example), plus 11 (that is, on 35); and it could check to see whether the square which was 11 past that, 46, was blank. If it found that all these conditions were true, the computer could jump over square 35 into square 46, and capture the piece currently occupying 35.

This, in essence, is how many computer board games -- from checkers, through reversi, to chess -- work, based on a simple 8 by 8 grid numbered in this way.

If you were writing chess on this board (as the chess game we'll look at shortly was, in fact, written), you could specify the moves of, for example, the knight, by knowing it can always move to squares which are the following 'numerical distance' from the square on which the piece now sits:

21 12 -8 -19 -21 -12 19 8

Try it now, by placing a coin on square number 55, and move it as if it were a knight, working out the mathematical relationship between the starting square, and the square you're moving to. You should find the differences are the same as the numbers listed above.

The programs in this section, and in many other parts of this book, were written in a 'top down' manner, in an attempt to produce a structured program which is relatively easy to follow and modify. Many of the programs were written by entering the following 'bare code' at the start:

```
10  REM NAME OF GAME
20  GOSUB 9000:REM INITIALISE
30  GOSUB 8000:REM PRINT BOARD
40  GOSUB 1000:REM COMPUTER MOVES
50  GOSUB 8000:REM PRINT BOARD
60  GOSUB 7000:REM HUMAN MOVES
70  Check if human has won or computer has
    won and if so branch to end of
    game message...
80  GOTO 30
```

This structure was written, in nearly all cases, before I had the slightest idea how I was to accomplish the goals I had set myself for each of the subroutines.

All programs were written out completely on paper before the computer was even turned on, so that a version of the game could be 'hand run' before starting to actually grapple with the game on the computer. This enabled the worst bugs to be caught right at the beginning.

I strongly advise you to follow a similar process when you write programs. I had read this advice myself, in several articles and books, and -- predictably enough -- had ignored it, until I found myself on a two week holiday in Wales, miles from the nearest computer store, with a burning desire to write a chess program. The program in this book is based on that original program, written on paper in a rented cottage on the Welsh coast, and dreamed up as my dog and I wandered for miles along the seafront.

Among the many great advantages I discovered regarding programming on paper in this way was the willingness with which I completely discarded whole blocks of code if they were found to be unworkable. It is much more difficult to decide to erase a whole section of code from a program once you actually have it in the computer than it is to just tear up a piece of paper. The temptation -- when lines of program are actually in the computer -- is to fiddle with them, in an attempt to make them work, at least after a fashion.

Working on paper, then, tends to avoid having code which really should not be in a program somehow being patched together to make it work. Working with a structured outline, such as that I've described, makes it simple to know which parts of the program carry out which task. I know, for example, in the

outline above that the board is printed by the subroutine starting at line 8000. Therefore, if the board comes out looking a bit odd, I know immediately which section of the code I should concentrate on.

As well as helping in the early 'get it working' stage, a structured program tends to invite improvements. Once you have, for example, your own Checkers program up and running, you can go back to it some time in the future to try and make it play a little better by going just to that part of the code which covers the computer's game. You will not have to wade through vast acres of code, trying to work out just what each line does, and which particular lines control the computer's play.

The methods I've just outlined are used throughout this, and most other sections, of the book. It may prove instructive to look through some of the programs to follow through the listing, and work out which section does what. In many programs, you'll see that I've included lines of asterisks as a REM statement. These break the program into separate modules which should help you follow the program through.

CHESS

CHESS is one of the greatest challenges which can face a computer programmer. To analyze how a human plays chess, and then to try and break that analysis into a number of ideas which can be expressed clearly enough to be written into a program, is a formidable task.

It cannot be claimed that this Chess program is a particularly successful attempt to surmount the challenge I've described. While it plays Chess on a reasonably coherent basis, it does not play well, and should prove no real challenge to defeat. Why then include it in the book, alongside other games which are practically unbeatable?

I've put the Chess program in this book precisely because chess has proved such an attraction to computer programmers. Very few Chess programs have ever been published (I know of one which appeared in Creative Computing magazine in December 1981, under the title Chess C.4, by Michael Rakaska; two others which appear in books; and the machine level listing of Sargon II) which suggests how difficult a task it is to produce a program of this type. I felt that the very rarity of published Chess programs gave weight to any argument in favor of including this one.

The possibility of a machine playing chess against man has occupied men's minds for hundreds of years. A chess-playing automaton, built by Baron von Kempelen which played its first exhibition match before royalty in Vienna in 1770, captured the imagination of much of Europe. Unfortunately, the machine was little more than an elaborate conjuring trick, with a man in a hidden compartment operating

the playing mechanism. It was a highly successful fraud, nevertheless, and an examination of its moves shows the man stuffed inside the device certainly knew his chess. While doing some research into the history of games-playing at the British Museum, I found in the British Library a book from the last century, 50 GAMES PLAYED BY THE CHESS AUTOMATON, which some earnest reader had annotated in the last 100 years. The human players came in for more scathing comments -- such as 'This move brands the player as a beginner!' -- than the machine ever received.

But despite its reputation, the machine could not really play chess. The first real approach to a device which would play a complete game of chess (as opposed to machines, a few of which were built early this century to play particular endgames) was in 1949, when on March 9 Claude Shannon, a research worker at Bell Telephone Laboratories, Murray Hill, New Jersey, presented a paper called Programming a Computer for Playing Chess at a New York convention.

As David Levy points out in his fascinating book Chess and Computers (Computer Science Press, Inc., Potomac, Maryland, 1976) the real significance of Shannon's paper lies not only in the fact that it was first, but that "many of Shannon's original ideas can still be seen in today's programs" (p.40).

Shannon said in that paper that the number of possible moves in a 40-move game approached 10 raised to the 120th power, a number which is of the same order as the atoms in the universe. Clearly any program which attempted to evaluate all those moves would be around a long time (say 10 to the 90th power years) before the first King's pawn made its foray out towards the centre.

To make this program play, and to get it to play reasonably quickly, demanded -- as I'm sure you can appreciate -- a number of compromises. I traded indepth evaluation against some rough and ready

playing ideas (such as programming the computer to move pieces to help hold the centre as much as possible; to develop knights as soon as possible in a game; to capture by a pawn, regardless of the fact that the pawn faced immediate capture, whenever possible; to hold the king as immobile as possible, at least in the early stages of the game, when a cowardly approach would seem to make good sense; and to allow pieces with vast mobility -- such as the queen -- a randomly-weighted decision-making mechanism which would ensure it did not sail off to the other side of the board, just because a clear channel was open for it to do so).

I followed a clear structure in laying out the program, which has ensured it plays as quickly as possible. The structure, in fact, is not as transparent as I hoped it would be when I first wrote the program. The complexity and number of demands put upon the computer by the game when I finally got the program up and running meant that my best-laid plans of producing a clearly structured program went somewhat astray. Nevertheless, the program does play extremely quickly, and if it does not play well, at least it is an opponent with quirks which can never fail to exasperate and amuse.

At the end of the listing there is a section which will tell you how to modify the program to get it to play against itself. This is a fascinating demonstration program, and one which never fails to arouse interest when it is up and running, especially from those who consider themselves experts at the game. I ran one game of 'auto-chess', with a printer connected, and before the listing, I'll show you that, so you can judge for yourself what sort of an opponent the computer will make.

The 'auto-chess' variation makes use of the exchange sides option within the game, swapping sides after each move. When you swap sides, as you can do if you feel the computer could do with some help, and

you'll give it the side you were playing on, the pieces are exchanged as if they were reflected across a mirror placed at the centre of the board. That is, a queen swapping sides ends up on the correct colored square, and so on. Try the exchange a few times when you're playing and the operation of this mechanism will be quite clear.

A final word, before we get down to our demonstration program. The computer must be watched to make sure it does not cheat. It will only do so extremely rarely, but (unless you're feeling particularly generous) if it -- for example -- moves into check you should take this as a sign that the program wishes to resign. Again, the machine sometimes has problems getting out of check. Here you may wish to be a bit more tolerant, as it will usually manage to do so within the next move or so. Alternatively, you can regard any such failure by the computer as an acknowledgement of your superior play.

Before the listing of the program, I'll show you a few stages in a game played by the computer against itself. The computer changed sides after each move, and printed the board after every second move.

If you wish to get the computer to play against itself, change line 2580 to the following:

```
2580 CLS:PRINT "Player"PR"at top of screen"
```

..and change the first 10 lines of the program so that they read as follows:

```
15 PR = 1
20 GOSUB 2970
30 GOTO 60
40 GOSUB 2580
50 A$ = "X"
60 IF PR = 2 THEN PR = 1: GOTO 80
70 PR = 2
80 IF A$ = "S" THEN END
90 IF A$ = "X" THEN PRINT "EXCHANGING SIDE"
  S":GOSUB 3540:A$ = ""
100 IF PR = 2 THEN GOSUB 3730
```

If you want the computer to trigger your printer from time to time during a game, to give you 'snapshots' of the program in action, add the following:

```
3730 IF RND >.08 THEN RETURN
3735 LPRINT "*****"
"
3740 GOSUB 3800
```

HOW THE PROGRAM WORKS

We'll have a look at a few parts of the chess program now, so that if you decide to modify it to improve its play, you'll know which bits to attack first.

As explained in the introduction to this section of the book, the program starts with a series of subroutine calls which are cycled through as the game progresses. After the first REM statement identifying the program, the computer goes to the subroutine from lines 2970 which initialises the variables. Next, line 30 jumps to line 60 which calls up the board printing subroutine at line 2580. This routine, like the other board-printing routines in this section, starts off with a clear screen (CLS) command. If you have a HOME key, or similar (such as PRINT @ 0, PRINT AT 0,0 or LOCATE 1,1) you should put this in the place of the CLS. Then the board will simply be reprinted over its old image, which gives a very effective impression of the pieces moving. It is far more satisfactory than clearing the screen each time the board must be reprinted.

After the board is printed, the program continues past line 60 into the computer move section. First it checks the status of A\$, which is a string set by the player after each move. If A\$ equals "S" then the human player has signaled a desire to quit the game, so the program ends. If A\$ has been set to "X" (for exchange) the program goes to the subroutine from line 3540 to swap sides. If A\$ is equal to "P", the computer moves to the subroutine from line 3730 which dumps the current board to the printer.

Now the computer play begins in earnest. Firstly, the T array (which will hold the location of the computer pieces) is filled with zeroes, and the piece counter variable (U) is set to zero. The loop in lines 150 and 160 goes through each square on the

board, counting the pieces (U is incremented each time a piece is found, and storing the location of each piece in the elements of the T array. When the king (variable KB, for 'king black') is found, the variable KM (for 'king marker') is set equal to that, so the computer knows where its king is at all times. If U is less than three (line 160) then the computer goes to line 2230 to concede the game. It has no endgame strategy, and tends to flounder if it has too few pieces.

Line 170 jumps the action to 650 where a long routine checks whether the king is in check. Each section of the code in this part of the program checks for danger from a particular piece. The first part, from 650 to 710 checks for danger from human knights while the next (730 to 890) looks for lurking queens, bishops rooks and pawns. If no danger has been found, so the program flow is not redirected by the numerous GOTOs in this section, line 890 sends the program back to 180 where it starts looking for a move.

Lines 180 and 190 reshuffle the contents of the T array, so that the king is the very last piece in the array. In general, the computer will try to move its pieces in terms of their position within this array, so if the king is at the end, it will only move if the computer judges no other move is worthwhile. As I said before the listing, this is one of my rough and ready chess-playing ideas and is based on the principle that if the king moves as little as possible, it is unlikely to get into danger. This, of course, is not always true. However, for the kind of chess the program plays it is a reasonable assumption, and certainly less dangerous than the alternative which would see the king belting around exposing himself to danger at every turn.

Now Q is set to either 0, 1 or 2 by line 210 and reset to 0 in line 210 if the human has signalled "C" for check. Q determines where in the T array the computer will start looking for its move. The random

element is introduced here so that the computer does not always do the same thing when confronted with similar board positions. One is added to Q if Q is less than U (that is, less than the total number of pieces the computer has on the board) and then Z is set equal to that element of the T array, which is the location of the computer piece on the board.

The subroutine at line 280 is now called. If you look at that subroutine, you'll see that lines 280 to 320 determine which piece it is dealing with. The computer plays black, and to make it easy to follow what is happening in the listing, QB is used to indicate the queen ('queen black'), RB is the rook, BB the bishop, NB the knight and PB the pawn. So the computer -- in this little subroutine -- just finds out what piece it has in hand, and then directs the computer to the relevant subroutine to check for a capture by that piece.

Now you should be getting an idea of how the program works. Essentially, it finds its pieces. If it is not in check it puts the pieces in an order dictated by the layout of the board (that will be explained when we get to the end of the program listing) with the king at the end of this list, then looks for a capture with each of the pieces in turn.

The most important variable (after KM, the king marker) is MM (which stands for 'machine move'). You'll see MM in line 240. MM is set initially to zero, and only gets reset to one when a move is found. Line 240 checks the value of MM and if it finds it is a one, knows that a move has been found, so goes to the subroutine from line 2500. Here it checks to see that (a) it is not trying to move its king without due cause; (b) that it is not moving a pawn unintelligently; and (c) that it is not just about to capture the human's king. Any of these three cases will cause the MM flag to be reset to zero,

and the action reverts to line 230 to find another move. (If the computer finds case 'c' is true, it prints CHECK on the screen, then continues looking for its move.)

If it finds that the three conditions are not true, then it actually makes the move (line 2530 makes the needed changes to the elements of the A array, the array that actually holds the board), then tells you -- using lines 2540 and 2550 -- the move it is to make, then returns to the start of the program where the board is reprinted.

If, however, MM was not equal to one when the computer came to line 240, it then moves on to 250 where the machine checks that it has not used up all its pieces (which will be the case if Q equals U) and if it finds it has not, goes back to line 220 where Q is incremented by one, and the process begins again. If, however, Q is equal to U, the computer decides it cannot make a legal move, to goes to 2360 to look for a non-capture move. The next section, as we've already discussed, sends the action to various parts of the program which control individual pieces.

If we look at the section from line 2360, we see that it starts by setting Q to a random number between zero and four. The use of the double RND ensures that it will tend to choose lower numbers in that range more often than higher ones. Z is set equal to the Qth element of the T array (as before when we were looking for captures) and then the lines from 2390 to 2440 send the program to the sections of code which control their moves.

We won't look at each of these sections for individual piece moves because each of them works in a similar way. Understand the basic principle of one, and you can easily deduce how the others work.

We'll look at the section which moves a knight, as we have already had some discussion (in the

introduction to this section of the book) on how knights move. Look at the section of code from line 1790. As you'll discover when we look at the initialisation section of the program, an array is set up for each piece which holds the possible moves (in terms of a numerical displacement from the starting square) for that piece. The Q array holds the possible queen moves, the B array the moves the bishop can make, and so on. Therefore, we know the N array, which is referred to in line 1800, holds the legal moves of the knight.

In this line, the variable X is set equal to Z (the square the piece occupies) plus an element (chosen at random) of the N array. Line 1810 checks to see that this possible 'destination' square is not off the board (which it would be if its value was less than 11 or greater than 88) or equal to 42 (which would also mean it was off the board). Y is the variable which counts the number of potential moves tried. It is incremented by one in line 1830, and then the computer checks the value now held by A(X), which is the destination square. If it finds it holds the value E (for 'empty') then it knows it can move into that square. But it does not necessarily just leap into A(X) just because this is an empty square.

First it goes to the subroutine from line 350 which checks to see if the intended destination square is under attack. On returning from that destination it checks (line 1850) to see if MM is equal to one. If it is, the computer knows the move it is considering has been approved, and so moves to the section of code which actually makes the move. If Y is greater than 20, which means 20 moves have been tried without success, then this also triggers a return, so a new piece can be tried. If both these conditions are found to be false, the computer goes back to line 1800 to get a new knight move at random.

In essence, this is how every possible move is generated, and tested. The knight is a little simpler than the other pieces because it can leap over intervening pieces. The other pieces have to check that a clear path exists for them to carry out their intended move, but this is not very difficult to achieve.

If you move now to the section of the program from line 2970, you'll see that the initialisation takes place here. First the computer asks the player to "ENGAGE CAPS LOCK...THEN PRESS RETURN". The computer counts how long this takes (using N as a counter) and uses this value to seed the random number generator. As in all programs in this book, if your RANDOMIZE function works differently from this, change the line to suit your particular dialect of BASIC. Line 3000 ensures that all variables will be treated as integer variables. This is included to maximise the running speed, but can be left out without harm if you do not have a DEFINT on your computer. MM (machine move, remember) is set to zero in line 3010 and A\$ (which holds messages from the player such as the desire to exchange sides) is set to the null string.

A number of arrays are now dimensioned. A holds the board itself, R the rook moves, B the bishop moves, N the knight moves, Q the queen moves, K the king moves, Z the exchange sides mechanism, S the priority sequence which determines the order in which squares are checked for pieces, and T the location of the pieces on the board before each move is made.

The next two lines initialise the variables which are the human and computer pieces as follows:

```
P - human pawn
R - human rook
N - human knight
Q - human queen
K - human king
E - an empty square
PB - computer pawn
RB - computer rook
NB - computer knight
BB - computer bishop
QB - computer queen
KB - computer king
```

The next line (3050) fills the A array (which will hold the board) with a dummy value (-99). This ensures that any square which is not subsequently given a value will be ignored when the program is running. This program, by the way, uses a numbered board similar to the one shown at the start of this section of the book, but it is 'on its side and back to front' with a layout as follows:

```
18 28 38 48 58 68 78 88 *8
17 27 37 47 57 67 77 87 *7
16 26 36 46 56 66 76 86 *6
15 25 35 45 55 65 75 85 *5
14 24 34 44 54 64 74 84 *4
13 23 33 43 53 63 73 83 *3
12 22 32 42 52 62 72 82 *2
11 21 31 41 51 61 71 81 *1
*****
A B C D E F G H
```

The next section of the program fills the arrays, with the Z loop (in line 3070) putting all the pieces in their place for the start of the game. The next section is fairly obvious when you examine it, with 3260 putting the values for knight moves into the N array, 3280 doing the same for the rook and 3340 for the bishop. The DATA pointer is then

restored to line 3290, the start of the rook information, so that the Q array (for the queen) can be filled with the locations for both the rook and the bishop because, of course, the queen is able to make the moves of both pieces.

Line 3430 fills the S array with the numbers in DATA statements line 3430 to 3510. These are probably the key reason why the program runs so quickly when it is underway. This series of numbers is the order in which the squares on the board are checked. If you compare this sequence with the 'numbered board' given on the previous page, you'll be able to work out the sequence. It starts with the squares in front of the starting position of the two key pawns followed by the squares either side of those, before moving back to look at the squares where the key pawns begin the game. Once you've worked through this list, you may well want to modify this sequence. This array, more than any other, determines the kind of game the computer will play. If you don't agree with the sequence I've set up, by all means change it and see what effect this has on the game the computer plays.

The 'exchange sides' routine is from 3540 to 3640, a series of comments when the computer loses a piece ("Great move, champ!" and so on) is generated by the routine from 3660 to 3720 and the final section of code dumps the current board to the printer.

GOMOKU

You'll find GOMOKU an easy game to learn, but one which is almost impossible to win. The computer plays extremely well in this program, which is based on one written by Graham Charlton.

You have to try to get five of your pieces (the H's) in a row in any direction, while the computer is trying to do the same.

Have a look at these board positions from the start of one game I played against the program. Studying the printouts will show you how the game unfolds, and will show you how to play it:

FOUR IN A ROW

In this game, FOUR IN A ROW, as its name suggests, the aim is to get four of your pieces (the H's) in a line in any direction, before the computer (using the C's) manages to do so.

You indicate your choice of move by specifying the column in which you want to move your piece. The piece then drops to the lowest available position within that column.

The computer plays this game fairly well, and surprisingly quickly, considering the number of times it can go through those loops within the program.

I was not particularly pleased when I finished the first hand-written version of this program, because it seemed to me that I had taken a 'brute force' approach to solving the problem. I was sure there would be a more clever way to do it. However, I continued with the program, and then entered it into the computer. It won the first game, even though it played a little oddly, so I knew I was onto a winner, despite the programming approach. Then, when thinking about it later I realised that if the program was correctly structured (as it was), had no redundant code (and it hasn't, as far as I can see), ran quickly and well, it did not need 'fiddling' to make the programming more tricky. Transparent code is always better than overly clever convoluted code which, although it may occupy less space, and may run a few microseconds faster, is almost impossible to modify.

So the program you have here is my 'brute force' version. It is generously supplied with REM statements so you have little trouble in working out what each section of code does. It should also prove fairly simple to modify, once you have played a few games with it in its present form.

In this version of FOUR IN A ROW, the computer always allows the human to have the first move, and bases its initial move on that made by the human. You may wish to modify the program so that there is an option for the computer to have the opening move.

Before we get to the listing of FOUR IN A ROW, here's one game played against the program:

CHECKERS

The game of CHECKERS has a long and honorable history. R. C. Bell (in his book *Discovering Old Board Games*, Shire Publications, Aylesbury, UK, 1980) says it was invented around 1100, "probably in the south of France, using Backgammon tablemen on a chequered chessboard with the Alquerque method of capture" (pp. 35 - 36). The *Encyclopedia of Sports, Games and Pastimes* (Fleetway House, London, c.1935) puts it much further back in time: "Forms of it were known in ancient Egypt, Greece and Rome, while the game was played in the mid-seventeenth century much as it is today." (p. 237).*

Regardless of its age, it is a very popular game around the world, with many European countries having regional variations on the game of their own. Continental draughts (checkers is generally known as draughts outside the US), for example, is played on a board of 100 squares with each player starting the game with 20 pieces. It was developed in the early 1700's.

This CHECKERS program plays the game you are probably most familiar with. It plays swiftly, and reasonably well, although its lack of endgame

*Both these books are very fine resources for game ideas to turn into computer programs. R. C. Bell's book (and others by this author) is particularly recommended. The 'Encyclopedia' has been out of print for many years, but you may find a copy of it in a secondhand shop. It was very widely distributed in the UK in the late thirties, and includes a host of fascinating information, including full details on how to build and fly your own airplane.

strategy often leads to a dramatic collapse in the final moment of a game.

CHECKERS is played between you and the computer. Each of you is attempting to take (that is jump over to capture, then remove from the board) the other player's pieces, or to confine the opponent's pieces so no more moves are possible.

The game is generally played on a board with 64 squares, which are alternately light and dark. In this program, the board (as you can see from the sample game we have shortly) is a series of dots, with your pieces shown as H's (for human) and the machine's pieces as C's (for clever).

When the game begins, you're at the bottom of the screen, playing up, and the computer is at the top playing down. As the program is currently set up, the computer always has the first move. If you want the first move then delete line 50.

All moves must be made along diagonals. Individual pieces can only move forward, that is towards the opponent's starting side. Pieces are converted into 'kings' when they reach the back rank across the board. Your kings are shown as K's, the computer's kings are dollar signs. Kings can move either forward or back. After capturing a piece, by jumping over it into the vacant square immediately behind the captured piece, you can move again if there is a further capture which can be made.

Here is a series of board positions from one game I played against the program:

SHOGUN

SHOGUN is based on the Japanese board game HASAMI SHOGI. In this game, generally played on the corner of a GO board, you move in any direction (forward, backwards or sideways) in a straight line. Diagonal moves are not allowed. As well, you can jump over a piece (again in a straight line). You can jump over your own pieces, or an enemy piece.

The jumped piece is not removed from the board. You capture a piece by squeezing it between two of yours. That is, you get one piece of yours on either side (except along a diagonal) of a computer's piece, and it is removed from the board. A piece is not captured if it moves between two of the opponent's pieces.

There are no double moves. You do not get an extra move following a capture. In the original game, the aim is to remove all your opponent's pieces from the board. However, this is a fairly slow game, and could take an eternity if played against the computer in this way. Therefore, I've written it so that the game is won by the first player to capture six of the opponent's pieces.

You'll find that the game will more or less teach you how to play it just by watching how it moves. Don't forget the fact that you can jump over your pieces, or the computer's pieces. This is a recommended tactic to get pieces well out into the board near the beginning of the game to get the game moving.

Here's the listing for SHOGUN:

AWARI

AWARI is one of a series of pebble-in-pits games generally known under the name of 'Mancala'. The game is played from Africa to the Philippines, and will now move into your home, via a very clever computer opponent.

As you can see from the sample game which starts below, the game begins with six 'pits' (the letters A to F and L to G) facing each player. Your pits are those from L to G. Each pit contains three seeds at the beginning of the game. Choosing any pit on your side, you pick up all the seeds from it, and then proceed to move in a clockwise direction, sowing a seed in each pit as you go past it. You do not sow any seeds in the pits at either end of the board, the ones which start off as zeroes.

If your final seed lands opposite an empty pit, then all the seeds in the pit you've landed in become yours, and are transferred to your 'home'. Your home is the zero to the left of the board, the computer's home is the zero to the right.

The game continues until either side is completely empty, so the player cannot move. At this point, the player with the largest number of seeds in his or her pit is the winner. The computer plays well in this game, but with practice you'll learn to defeat it. Don't expect too many victories in the early games. Remove the INPUT Z\$ in line 270 if you don't want to see the computer's move before it is made. Also, you can delete the loop in line 40 to get maximum speed (although the computer plays very swiftly even in its present form).

Here's a game I played against my own computer:

A	B	C	D	E	F
3	3	3	3	3	3
0					0
3	3	3	3	3	3
L	K	J	I	H	G

I'll move from C

KNIGHTSBRIDGE

KNIGHTSBRIDGE is one of the few games which I can claim I invented completely (although, of course, the idea of naming it after a London suburb came from the two inventors of KENSINGTON). I make a habit of reading games books to get ideas, and often when I walked in the woods around London, I'd take a book with me to read when I felt like a rest. I was walking one Sunday afternoon near Ruislip Lido thinking about a passage I'd just read in a book which said that Chess evolved from an Indian game in which the throw of a die dictated which piece was to move.

From that starting point, I thought of a game in which all the pieces were Chess knights (hence the name of the game) and a die was used to say which piece had to move. KNIGHTSBRIDGE evolved from that idea.

It is played on a seven by seven board. The computer tells you which piece you must move (each piece is indicated by entering a two-digit number, the first being the co-ordinates of the square you're moving to down the side of the board, the second digit being the co-ordinates of the square across the top), and then leaves you to decide where you will move to. All pieces move like Chess knights, and all moves are checked to see if they are legal before you are allowed to move.

You capture by landing on top of an enemy piece. The first player to capture five of the enemy's seven pieces is the winner. There are no multiple jumps.

You'll find the computer plays swiftly and well.

Here's the inventor of the game being thrashed by his own invention:

REVERSI/OTHELLO

The final program in the boardgames section of this book is REVERSI, which is often called OTHELLO. Invented in the late eighteen hundreds, it is played on an ordinary eight by eight board. When played on a board, you use pieces which have different colors on each side. The game begins with four pieces placed on the centre squares.

From this point on, you move by placing one of your pieces next to a computer piece or pieces, with another of your pieces further on. When that happens, all the computer pieces 'reverse' to become your pieces.

Here's how it works. Suppose a line of pieces looked like this:

OXXXX

...and you decided to put your piece (the O) at the end of the line like this:

OXXXXO

The computer pieces would reverse, so the line looked like this after your move:

O00000

The game continues until every square on the board is filled, or neither player can move. As you can see, fortunes can change swiftly in this game, as rows branching off your position (such as on the diagonals) can be changed with a single move.

If you cannot move at any time, you signal this to the computer by entering a zero.

Reversi is a very enjoyable game to play. Writing in Creative Computing magazine (June 1981, p. 188)

David Levy tenders the opinion that it is "one of the best games ever invented, simply because the rules can be learned in no more than a minute, yet the game can take years to master". He goes on to observe that although the game is much simpler than chess, it is more complex than checkers.

Although the modern game is called Othello, and was 'invented' by Goro Hasegawa in Tokyo in 1971, the only difference between it and Reversi is the fact that the first four positions must be as in the sample game you'll see following this description.

Back in the 1880's, when the game was first invented in London, two gentlemen -- Lewis Waterman and John W. Mollett -- both claimed to be the originators of the game. Stephen Kimmel (writing in Creative Computing magazine, July 1981, p. 94) says he believes Waterman has the strongest case for being the inventor of Reversi, because he had the details published first in a series of articles in the magazine, The Queen (which concentrated on "affairs of interest to ladies").

Regardless of who should get the credit, Hasegawa, Waterman or Mollett, it is a great game, and this program (based on one written by Graham Charlton) puts up a spirited defence. This sample run shows the early stages of one game:

Othello is a registered trademark of Gabriel Industries, Inc., USA and Mine of Information, UK.

Adventure

Adventure

Down into the depths of darkness you go. Armed with only your computer, and your keen mind, you have decided to take on the forces of evil.

You may be on a desert island, inside a haunted house, within a dungeon deep within the bowels of the earth, or trapped in a cave system on a planet 'somewhere in a galaxy far away'.

ADVENTURE games take place in all these scenarios, and a thousand more beside. Come with us now, as we discover the excitement of the worlds of ADVENTURE.

The word ADVENTURE is used to describe the class of computer games in which the player moves through an alternative reality. In this 'otherworld' there are monsters to be fought, treasures to be discovered, maps to be made, and puzzles to be solved.

Many people feel that ADVENTURE games are the most exciting games which can be played with a computer. If you are interested in role-playing games like TSR Hobbies' Dungeons and Dragons (the game and name are registered trademarks of TSR), then you're certain to enjoy playing ADVENTURE.

I've included three ADVENTURE-like programs in this book. Two are of medium difficulty, and the third one -- a massive program occupying more than 16K -- should have you scratching your head as you try to work out what is going on.

One feature of true ADVENTURE games is that the reality they model is consistent. That is, the world created within the ADVENTURE program is solid, and -- apart from any events specific to that game, such as an earthquake, or a magic spell -- the parts of

the world do not shift in a random fashion. If you walk past a 'gnarled and twisted oak, with the initials of your best friend carved in the trunk' when going down a certain woodland park, the same oak should still be there when you return. In a properly constructed ADVENTURE the rivers stay in place, the dungeon walls do not mysteriously move and shift every time you turn your back, and objects you put down in one cave within an underground labyrinth do not suddenly appear of their own volition a hundred caves away (unless, of course, they've been blessed with some form of magical auto-transportation).

Map-making is one of the true ADVENTURE-players skills and delight. Working your way through an imaginary (but self-consistent) environment, tackling monsters and collecting treasures, solving puzzles as you go up and down staircases and chutes, explore side tunnels, get lost in self-circling mazes, and so on is only fascinating if the world you are exploring is mappable. You should, for example, be able to expect both ends of a tunnel to always emerge in the same spots, so when you come across one entrance to that tunnel later on in a game from a different position, you will have a new, useful clue to further flesh out your map of the environment. All the 'worlds' created in the games in this section of your book are mappable, and the first two even give you glimpses, from time to time, of the scene from above. The third one does not, and this is the one you should tackle last of all, once you're confident you can move through the other, much simpler, environments at will.

Role-playing is part of life. There are sure to be many situations in your everyday activities when you, to some extent, are forced to adopt a role. Most jobs, unfortunately, expect you to behave as if the needs and goals of the company were your own needs and goals, that the enthusiasm you project each day to customers and fellow-workers were your own, inner enthusiasms, and so on. You may well

find that, in new situations, you have learnt to mask your lack of ease by acting confident, and at ease, discovering that -- if you do it skillfully -- people take the projected role as if it were your true self.

The role-playing which takes place within the imaginary environments of an ADVENTURE game is far more interesting, and is generally far removed from the self of your everyday life. When you think about it, even playing games like 'Cops and Robbers' is an exercise in role-playing.

So, we've all had experience in role-playing, even if some of it was not as much fun as taking part in long-range campaigns to rescue a handsome prince, trapped within a tower. The ADVENTURES given in this book are by no means as elaborate as some of the ones offered for sale for your computer, but they are more carefully and consistently organised than many I have seen, and -- as a bonus -- give you frameworks within which you can construct ADVENTURE programs of your own.

Role-playing games which involve other people, such as TSR's D & D which I mentioned earlier, generally have a great deal of flexibility in development as a game proceeds. Under the control of a good Dungeon-master, a role-playing game can develop and evolve in directions which he or she had not even imagined when setting up the initial scenario. Unfortunately, computer role-playing games cannot be so flexible. In many ways when playing ADVENTURE with a computer, you are trying to solve a puzzle, or series of them, which the programmer has created. The computer can be used to help set up the initial scenario and determine where objects will be located, and perhaps where a particular stairwell will lead, but the overall shape to the environment is fixed by the programmer when the game is written.

You can see this in action, for example, in our program STRONGHOLD OF THE DWARVEN LORDS where you

have to work your way through a maze to discover where the Dwarven treasure is stowed. The computer actually hides the treasure, and modifies the '3-D maze' to some extent, but that is all. Of course, the computer is also used to produce the feedback to the player as the game is underway, and its role there is very valuable.

Once upon a time, war campaigns were re-enacted on table tops. Napoleonic battles were fought and won on large sheets of card marked with rivers and woods, as players re-enacted major engagements within wars, or created their own. Wargamers found the pleasure of the games they played could be increased if attention were paid as much (if not more) to the individuals they were fighting with, rather than just with squads of soldiers. This attention to individual identity lead directly into the role-playing games we have today, as gamers discovered how rewarding it was to take on the role of a particular leader.

Our Dungeons and Dragons developed directly from the war games where players took on the identities of individuals within battles. Two gamers, Dave Arnsen and E. Gary Gygax decided to codify an entirely separate reality, which they initially gave to the world in 1974 as a boxed set of three booklets under the title Dungeons and Dragons. The game became an enormous success, and now hundreds of thousands of people spend a significant portion of their leisure plunging into the depths of the earth, as clerics, trolls, magicians and sorcerers, exploring, fighting, conquering -- and occasionally dying -- as they go.

The original D & D idea soon spawned a host of other games, such as Runequest (Chaosium Ltd, Albany, California), Bushido and Chivalry & Sorcery (Fantasy Games Unlimited, Roslyn, New York), Tunnels & Trolls

(Flying Buffalo, Inc., Scottsdale, Arizona), Traveler (Game Designers' Workshop, Bloomington, Illinois) and Heroes of Olympus (Task Force Games, Amarillo, Texas).

Will Crowther and Don Woods entered computer history in 1976 by putting the world's first role-playing game -- just called ADVENTURE -- onto a mainframe computer at Stanford University. (The program was actually written by Crowther, and elaborated by Woods, although today both men are generally credited with developing in the program.) Although the game quickly became a cult-pursuit all over America, the floodgates to computer ADVENTURE-gaming did not open until microcomputers put machine-power -- and computer time -- into the hands of millions. Cheaper memory enabled extremely elaborate adventures to be created, and so now the computer ADVENTURE gamer is extremely well served.

Crowther and Woods perhaps created better than they knew. Even today, despite the multitude of programs available, the original ADVENTURE is still going strong. At least five companies at present are selling versions of the original ADVENTURE for the Apple alone.

This original program was written in Fortran, and when it was added to a free software-exchange library (Decus) organised by the Digital Equipment Computer Users' Society (most of whom used Dec's DCP-11 systems), it soon became the most-used program in the library. Two years later, another adventure program, Dungeon was added to Decus. This program which took the ADVENTURE idea much further than Crowther's program, was written by Tim Anderson, Marc Blank, Bruce Daniels and Dave Lebling, all of the Programming Technology Division of the MIT Laboratory for Computer Science.

The Addison-Wesley Book of Apple Computer Software (edited by Jeffrey Stanton and John Dickey, The Book Co., Lawndale, California, 1981) devotes 29 pages to

describing fantasy, role-playing, adventure and war simulation games available for the Apple II. If the support for that computer is so good in this field of software, it indicates that many other popular computers are also well-supported.

Even so, despite the ADVENTURE programs you can buy for your computer, the thrill of creating your own programs for this most special of computer games is one which you should experience. And the programs given in this part of the book will certainly give you a framework upon which to build. I suggest you get them up and running, and then elaborate them to your heart's content (or at least until you run out of memory).

Although there is a trend towards graphic-based adventures, rather than the classic text-based ones, the attraction of text programs continues. Just as television did not make radio obsolete -- because the imagination is stronger than anything man can make -- so graphic adventures have not taken away the special value of text-based games, where the mind is triggered to produce worlds far more fantastic than any that a clever programmer could draw using the sophisticated graphics available on many of today's machines.

However, you'll probably find you can make the presentation of the text output of these games more attractive on your computer by adding color and sound as you see fit, using the special features of your machine to enhance your enjoyment when playing the games.

One of the leading companies in the world producing ADVENTURE programs is Adventure International, founded by Scott Adams. His company has some of the most imaginative displays at computer shows of anyone in the games software field, and it is good to know his programs are as exciting as his show displays. Make sure you experience the pleasure of playing a Scott Adams adventure program in due

course, and you'll see how far the genre has been extended.

I met Scott in Atlanta one day at a computer show and found him friendly, quiet and reserved. Somehow, I'd expected him to be like a warlock from one of his dungeons, or a dragon from one of the cave systems. However, some behaviour was more in keeping with my expectations. It was Halloween, and Scott and his crew were all dressed to the nines as characters out of some of the programs. The same approach to life which had him tell his staff to come to work in fancy dress permeates his programs. Start with the programs here, which are much simpler to solve than programs such as Scott's, and then graduate to the commercial programs. Perhaps his program Adventureland would be a good place to begin, before you move on to some of his other games, and onto those produced by other companies.

Avalon Hill's program Empire of the Over-Mind is another of the classics of the field, and this -- as well as Sentient Software's Cyborg deserve inspection. The list could go on and on, and certainly new titles have been added to the programs now available, so your computer magazines and/or your local gamer and computer clubs would be a good place to find out just what else is around for you and your computer.

I guess it's time now to introduce you to the adventure programs in this book. If you'd like to know more about the field, to help you write your own programs, there is a vast body of literature which is of interest. It includes:

- PUTTING ADVENTURE IN ADVENTURE GAMES - article in Creative Computing, August 1981, by Robert Plamondon
- GRAPHIC ADVENTURES ON THE ATARI - article in

Creative Computing, August 1982, by John Anderson
- FANTASY GAMES (parts one and two) - articles in Creative Computing, issues of March 1981 (part one) and May 1981 (part two) by David Lubar

- AN ADVENTURE IN SMALL COMPUTER GAME SIMULATION - article by Scott Adams (when he was just about unknown!) in Creative Computing, way back in August 1979

- KINGS OF THE CASTLE WALLS - article in Practical Computing, March 1982, by Dennis Ellis

- ADVENTURE WRITING - this is an immensely valuable 16-page booklet, distributed by Aardvark-80, 2352 S. Commerce, Walled Lake, MI 48088 (313 669 3110) for around \$5.00. It explains the whole background of adventure game writing, and includes a complete adventure program, Deathship. If you read nothing else in the field, you should get hold of this booklet if you really want to discover how to write adventure games

- FANTASY ROLE-PLAYING GAMES - Holmes, J. Eric (Hippocrene Books, Inc., New York, 1981)

- WHAT IS DUNGEONS AND DRAGONS? - Butterfield John, Parker Philip, and Honigmann David (Penguin Books, New York, 1982)

- DICING WITH DRAGONS - AN INTRODUCTION TO ROLE-PLAYING GAMES - Livingstone, Ian (Routledge & Kegan Paul, London Melbourne and Henley)

STRONGHOLD OF THE DWARVEN LORDS

dusty stacks of uncatalogued manuscripts in room Deep beneath the earth you go, far into the Dwarven Heartland. Danger is on every side as you descend, but your greed draws you on. Searching through the dusty stacks of uncatalogued manuscripts in room 546B of the British Museum, you came across a faded, and almost illegible map to a Dwarven hoard of gold, and since that day, you have been obsessed with the idea of finding it.

As you go down into the labyrinth, you realise that the Dwarven Lords, who secreted the gold here 7389 years ago, have long since become extinct, so the main danger you face is from the layout of the cavern system itself, rather than from Guards of the Stronghold.

In STRONGHOLD OF THE DWARVEN LORDS you are in a cavern which holds the gold. Each time you play this game, the gold can be in one of three places. The only information you get as to your progress is information provided by the Dwarven Source Beam which you found as you made your way into the cave system. This gives you feedback after each move as to the location of the gold, but you need to learn how to interpret the information it gives you before you'll be able to make much use of it.

The other information you get is in the form of a

straight statement regarding the directions you can move from your present position. After each move ('step'), you'll be given a screen display like the following:

STEP NUMBER 49

NORTH: WALL
SOUTH: OPEN
EAST: WALL
WEST: OPEN

THE DWARVEN SOURCE BEAM READS 10

Then you'll be asked to enter the direction you want to move, as follows:

Which direction do you want
to move?

N - north, S - south
E - east, W - west, H - help
? W

You will not, as you probably realise, be allowed to walk through walls.

The aim of the game, needless to say, is to reach the Dwarven riches as quickly as possible. To aid you, there is a map of the cavern system from above,

which you can call up from time to time. The map looks like this (with the walls shown as # symbols, and you shown as *):

```
North
#####
# #####
## #####
## #####
## #####
## #####
#####
#####
## *
## #####
## #####
#####
#####
#####
#
#####
South
```

There are two catches to calling up a map of this type. Firstly, although you are shown, the location of the gold is not. Secondly, each time you enter 'H' to get a look at the map, you'll be penalised 15 steps. Therefore, it is in your interests to use the Help option as few times as possible.

Although there are some features which are common to each and every cavern generated by this program (dictated by the data statements from 870 to 960), the cavern is not identical from run to run. As well as that, as I mentioned earlier, the gold itself can be in one of three locations within the cave system.

The output of the program, as it is given in terms of the directions you can take from your present position, could be modified to produce a '3-D maze' output. You know, from move to move, which direction you're facing, and the computer knows

which directions from that position represent possible moves. You would need to add a subroutine which drew a picture of the situation immediately in front of you, choosing from a bank of pictures (one with the area straight in front of you clear but with the walls solid on either side of you, another with extrances to the right and to the left but with the path straight ahead blocked off, and so on) to produce a continuous picture of the scene ahead. This can be most effective, and may well be worth implementing on your system.

Now, here is the listing of STRONGHOLD OF THE DWARVEN LORDS so you can start trekking for gold:

```

THE DUKE OF DRAGONFEAR

THE DUKE OF DRAGONFEAR puts you into another grid system world, but one which is populated with a range of fearsome possibilities including pits containing quicksand or dragons, as well as magic caves which can transport you at random within the land of Dragonworld, and caves filled with Dragon's gold.

When you first run the program, you'll get this information:

Welcome to the world of Dragonfear

Your mission is to explore the caves of Dragonworld, looking for treasure, and attempting to slay the fearsome dragons who live in the caves. What is your name?

All hail, Duke Tim

You start this exploration with 25 units of charisma, and you must complete your task before the charisma is worn out. You lose one unit for every move you make

PRESS ANY KEY TO BEGIN

Having assimilated this, you are given a quick peek at a map of Dragonworld:

```

X X X X X X X X X
X . D D $ ? D . . X
X D X . . X . . . X
X D . . . . Q . X X
X Q . . $ . . . ? X
X . . . H . . $ ? X
X $ $ . . . X . ? X
X . X . . . . . X
X . Q Q . . . . . X
X X X X X X X X X

```

In this map, X represents a wall you cannot pass or a cave you cannot enter, H (for human) is you starting in about the centre of the system, \$ is the treasure caves, ? the magic transportation caves, D represents dragons and Q tells you that cave contains quicksand. Obviously this is a world filled with potential pleasures as well as dangers.

If you're a veteran of computer games, you may well recognise that THE DUKE OF DRAGONFEAR is a development of the Hunt the Wumpus games. Wumpus is one of the grand old standards of computer games, in which you are in a cave system, looking for one or more mythical beasts known, in the singular (and these are most singular beasts) as Wumpus. Wumpii we are assured, by those who care about such things, is the plural. Anyway, in essence, a grid is set up in such games, and objects, people, effects, monsters and whatever else you choose is placed at locations on the grid. From time to time, if you so decide, one or more of the contents of specific cells of the grid may move. The human player, of course, can also move from cell to cell within the grid.

Generally, there is no overall visible map of the system, although some programs (such as THE DUKE OF

DRAGONFEAR) do provide such information for players. The very first Wumpus game was written by Gregory Yob in 1975. In David Ahl's superb book More BASIC Computer Games (Creative Computing Press, Morristown, New Jersey, 1979), Mr Yob explains how he was visiting People's Computer Company, in Menlo Park, California, to see the programs they were developing, and he noticed there were three 'hunt the something' programs being written, each on a 10 X 10 grid, and each of which gave feedback to the player in terms of 'no, no...try to the northwest'.

Unenchanted, Mr Yob returned to a lonely time-sharing terminal (back in those ancient days, gentle reader, human beings did not have little computers at their beck and call) and hammered out the program which eventually became the very first 'Hunt the Wumpus'. Mr Yob had the creature dwelling in a docehedron-shaped cave system.

Mr Yob's inventive genius did not stop at this point. He peopled the cave with 'magic bats' which moved you from place within the system at random, with bottomless pits, and ensured that the arrows with which you were equipped when you entered the system could fly round corners.

You can see now how this framework became the heart of the Wumpus programs which have proliferated around the world and which formed the very rawest framework upon which THE DUKE OF DRAGONFEAR is based. This program gives you more control on the outcome of the program, adds treasure to the caves, and imposes a time-limit to your game.

As well, you are equipped with a 'magic amulet' which can see into the caves which are around you. Unfortunately, because you're not much of a whizz when it comes to envoking magic, the old amulet doesn't work too well. It can only tell you of the contents of one of the eight caves surrounding the one in which you stand, and worse than this does not tell you which of the eight it is referring to. It

is not as bad as it may sound. You'll be surprised at how much use you can make of the limited information the amulet provides. As well, you'll get a brief glimpse of the cave system from above at the start of the game, and from time to time as it goes on.

As you can see from the sample run which follows this introduction, your options at each move include 'F' to fight. Pressing 'F' will direct the program to the subroutine starting at line 930, which first checks to see you have not used up all your arrows, and if it finds you have not, allows you to choose in which direction -- from your present position -- you want to fire the arrow. A successful kill earns you a handsome monetary reward.

Here are some snapshots of the program in action:

```

THE BANNOCHBURN LEGACY

As I pointed out at the start of this section of the book, when you write an Adventure program, you are actually (if you do the job properly) constructing an alternative reality, with its own inner consistency and rules. In an Adventure program which plays by the rules, an object placed in one room will stay there until you move it, the walls in the haunted house you're exploring will not move and shift around you every time you turn your back, and streams and rivers won't change their course each time you decide to cross them.

Our next program, and the final one in this section, THE BANNOCHBURN LEGACY, is far closer to the 'standard' Adventure programs we discussed in the introduction. In this program, all activities (except for the very beginning) take place with Bannochburn Castle. The castle contains a number of monsters, including 'an angry warlock' and 'a fire-breathing Fearbringer' who wander throughout the castle while you are playing the game, waiting for the chance to leap upon you, and tear you limb from limb. The castle also contains bottles of magic potion, chests which contain good and bad surprises, sheets of papyrus with magic spells written on them, and more besides. To tell you of everything you will meet would diminish the game somewhat.

You are unlikely to come across all the contents of the castle in a single play of the game. As well, the monsters have different powers each time you tackle the adventure, and the chests and the gilded safe, along with the rest of the magical contents, are in different locations. Although the monsters

wander from room to room while you're playing, the contents do not appear and disappear at random. Once you've opened, for example, chest number two, you'll never see it again during that game. If you wound a monster in combat, and you come across him again later in the game, you'll find it is the very same (wounded) monster that you attacked earlier. Things like this help to aid the 'reality' of the fictional universe.

You will not be given a map of the castle. Part of the pleasure of adventure gaming comes from actually working out how each part of the 'adventure universe' is related to the other parts, and map-making is one of the skills you will probably enjoy developing. Castle Bannochburn was mapped carefully before the program was written, to ensure that the rooms actually did match up in a coherent manner, to encourage you to map the castle as you explore it. Once you've got a reasonable map worked out, you may well want to test it by 'wandering through' the castle from room to room.

The aim of the game is to find the Black Lagoon, which lies beneath the castle, but is entered from an ordinary-looking door in the castle. The location of the Black Lagoon can change from game to game, although it will not move once a game is underway. This ensures that your interest is maintained in the game, even after you first manage to map it.

You are endowed with three 'attributes' when you play the game:

Magic - Strength - Wisdom

You play the whole game in terms of these attributes, choosing to battle each monster in the particular attribute in which you feel strongest, and in which you feel the particular monster is weakest.

Your attributes change and develop as the game progresses, gaining when you win a battle, and diminishing when you lose one.

When you first run the program, you'll see the following:

TIM, your attributes are:

Magic: 1

Strength: 5

Wisdom: 2

You are at the entrance to an ancient, forbidding-looking castle. You are standing on the north side of the castle, and as you look south, towards the tumbling structure, you notice the entrance portal is open and unguarded.

What do you want to do now? S

The final question "What do you want to do now?" comes after most room descriptions in the game, and you need to give one of the following eight answers:

- N (go north)
- S (go south, the answer you must give to the first frame, shown above)
- E (go east)
- W (go west)
- F (fight - this is one of the two possible answers you can give when confronted by a monster)
- FL (flee - this is the other answer, and it is not always accepted; "No, you must stand and fight" you'll be told)
- Q (quit - this is used if you wish to end a game before the end)

The only answer you'll need is "Y" or "N" to answer questions like "Do you want to open the chest?".

This program is largely self-running, and takes care of many of the tasks which a Dungeon-master looks after in a role-playing game with other people.

One of these tasks is the running of the battles, or melees, which occur during the game. All fights are resolved according to the relative strength of the protagonists in the battle, and on the result of a throw of a die which is weighted to favor the stronger of the two squaring up to fight. You should therefore always select the attribute in which you outrank the monster, to increase your chances of winning that particular fight.

The point of the game is to get out of the Black Lagoon alive. In the final fight, against the Guardian of the Black Lagoon, you must have three fights, one with each attribute, and you must finish this three part fight with a total of at least 10 attribute points. The money you collect within the castle can be used, just before the final fights, to buy additional attribute points.

To tell you much more would detract too much from your process of discovery when you play the game. All I need to do is assure you that the castle layout is mappable and coherent, and it is worth the trouble to try and work out the layout of the castle. Note that this program occupies more than 16K, so the PRINT statements may need shortening to get it into your system, making sure you also leave working space as well as allowing for the length of the listing.

The story of Bannochburn Castle is simple, but tragic. In the famed War of the Clans which ravaged northern Scotland in the closing years of the 15th Century, the Laird of Bannochburn engaged the services of Wee Sporrán McMerlin, a sorcerer originally in the employ of King James in the Edinburgh Court. When the bloodthirsty McKinna Clan joined forces with the equally intemperate McClaren hordes, and together attacked Bannochburn, the Laird employed McMerlin to invoke a spell to protect the castle forever.

Unfortunately, Wee Sporrán's intelligence was not as good as his magic, and instead of conjuring up some spells to look after the inhabitants, he simply conjured up a storm to protect the castle. The Laird and his retainers were slaughtered, but the castle remained intact. It survived right to this day, and your task now is to explore it, and try and seek out its secrets and gold, and to slay the Guardian of the Black Lagoon so the current Bannochburn Clan (now living above a dry cleaner's in Glasgow) can regain their rightful inheritance. You feel -- possibly rightly -- that they'll be pretty grateful to you if you manage to slay the Guardian, and thus rid the castle of the spooky inhabitants Wee Sporrán placed within the walls so many years ago to protect it.

Note that once you enter the castle, there is no way out but through. You cannot leave again by the front entrance, so there is no room for second thoughts. All input must be in upper case, so you must ensure your computer is working in upper case before running the program, or all your precious input will be ignored.

Good luck, and may the Guardian fall to your mighty powers.

Here are a few samples of the program underway:

You've tripped in the dark.

Something awakes. Oh, you're face to face with Gravelpit, the Kneecrusher, who has magic of 1 strength of 4 and wisdom of 1

What do you want to do now? F

Which characteristic will you fight with?
Your magic is 1, strength is 5
and your wisdom is 2
? S

The fight table for this melee reads 1

The melee carries a cost/reward of 7

You attack first, and the battle is joined...

Rip

Tear!

The Kneecrusher defeated you

After that fight, your attributes are:

Magic: 1
Strength: 0
& Wisdom: 2

And those of the Kneecrusher are:

Magic: 1
Strength: 11
& Wisdom: 1

TIM, your attributes are:

Magic: 3
Strength: 15
Wisdom: 2

This is the most magnificent room in the castle, the Great Hall, with a massive hammerbeam roof. You can leave it by the double doors to the north or by those to the east behind which you can hear music playing. Through the windows in the west wall, you can see the Contoured Garden, and beyond that, through windows of a room hung with many, many fine paintings

In front of you is a chest labelled with a large # 1

Will you open it?

A goblin leaps out, stabbing you!

And this is the complete listing

Simulations

Simulations

Simulations are ways of producing a counterfeit reality. In contrast to ADVENTURE, where the reality created via the computer is often magical and dream-like, the worlds accessed through computer simulations are generally more down to earth.

In a simulation, the computer manipulates variables in accordance with formulae you've specified, keeping tabs on the unfolding of the situation you've generated, and taking the place of the environment in terms of reacting to your input.

Simulations attempt to replicate life. However, because reality is notoriously hard to pin down and limit, we need to do some pretty drastic simplification before we can produce a workable simulation.

Despite this simplification -- as you'll soon see -- a well-written simulation can imitate life to an uncanny extent. Cause and effect are linked as accurately as you can devise formulae for them. The random number generator can take the place of such things as changes in the weather, in population numbers, in the behavior of molecules in a gas or the way a colored ink is dispersed through a clear liquid.

In this section of the book we have three simulations. One of them -- MISTRESS OF XENOPHOBIA -- is simple to the point of absurdity, but it is great fun to play, as you tinker with the fate of an entire planet. The other two -- RURAL PURSUITS (where you run a farm with extremely fickle workers) and CHAIRMAN OF THE BOARD (where you run a factory that could produce any one of a range of products including kazoos, pith helmets or sky hooks) -- are a little more serious, and the formulae employed in them produce results a little closer to 'real life'.

Despite the seriousness of the last two I mentioned, they are still great fun to play, as you'll see when you get them up and running on your micro.

If you want to know more about writing simulations the booklet Designing Classroom Simulations by Glenn Pate and Hugh Parker, Jr., will be of help. As well, Creative Computing magazine has printed two articles which are very valuable. These are "How to write a computer simulation" by the magazine's erstwhile editor, David Ahl, which appeared in the Jan/Feb (1978) issue of the magazine (and is the text of a talk David presented at the Conference on Computers in the Undergraduate Curricula in Pullman, Washington, in June 1974), and "Strategies for Successful Simulation" by Bruno B Wolff, Jr. which was in the August 1981 issue. It is worth checking your library for these back issues, as you'll learn a lot of value by reading them. Of particular interest in the Wolff article is a set of four equations which link cause and effect and can easily be adapted for a simulation you write.

MISTRESS OF XENOPHOBIA

We'll start our exploration of simulations with the silliest one of the lot, MISTRESS OF XENOPHOBIA, which is based on a program written by Alastair Gourlay, a talented programmer who lives in Glasgow.

There's no need to explain MISTRESS, as the program gives you all the prompts you could need. Here's part of one run:

Mistress of Xenophobia, a report for
you from the Office of Information
regarding the state of your planet
in this year of Grace, 1995

The planet's population is 440

The grovelling peasants could work
some 119 acres this year...

Your treasury holds gold, gems
and coins worth \$ 1049

Time to issue a decree...

How much land is to be farmed
this year? 27

The grovelling peasants could work
some 268 acres this year...

Your treasury holds gold, gems
and coins worth \$ 2204

Time to issue a decree...

How much land is to be farmed
this year? 24

And how much will you spend
on food for the peasants? 24

Oh dear!! There's not
enough food for everyone...

Horrors, your Xenoness
There's been a rebellion!!!
The peasants are revolting
(I had to get that line in!)

Your treasury holds gold, gems
and coins worth \$ 890

Time to issue a decree...

How much land is to be farmed
this year? 100

Well, Xeno, that's a fine
mess you've got yourself, and
our little planet into.

The Treasury is bankrupt!!

Guess who blew it??????????

If you'd like another shot
ruling, then just press 'Y' or
press 'N' to end this farce..

And this is the listing:

```

RURAL PURSUITS

If you've survived being MISTRESS OF XENOPHOBIA, you may be interested in something a little more earthy -- running a farm. In RURAL PURSUITS, based loosely on a program written by Stephen Glen, also of Glasgow, you have a very difficult task, as you battle with an extremely touchy work-crew to bring home the bacon (or at least the wheat and barley).

Again the program is largely self-prompting, and working with it will teach you the best strategy for gaining a maximum return from your farm (and surviving for the requisite 20 years to win the game). However, a few hints will not go astray. Although you can save money by paying your workers extremely badly, you'll find they'll desert you in droves in the following year, and the return you get from your land is dictated, to some degree, by the number of people you have working on the land.

Another factor to keep in mind is that the three crops which you can plant have quite different returns, so it is in your interest to work out which is the most profitable crop, and concentrate on that.

Do not be dismayed if you foul the process up the first few times you run the program. You'll have to develop some real skills to keep your farm solvent, and it may take you several bad years to get the hang of it.

Here's part of the output of RURAL PURSUITS:

You have \$ 7203 in year 1

You are employing 484 laborers, working for you on 351 acres

Crops:-
0 corn
0 barley
0 wheat

It will be \$ 10 in general costs to work each acre...and so the maximum number of acres you can work this year is 351
How much land do you want to harvest? 100

You have \$ 6203 in year 1

How much will you pay each worker? 11.50

You have \$ 637 in year 1

What proportion (out of ten) do wish to concentrate on corn? 3

Of the remaining 7 out of 10, how much wheat will you plant? 5

Crops:-
265 corn
33 barley
418 wheat

716 tons were harvested

And your total return was \$ 2781

And here's the program so you can become
a happy farmer:

```

CHAIRMAN OF THE BOARD

Finally in this section we have our major simulation, CHAIRMAN OF THE BOARD.

Again the program is largely self-prompting. The aim of the game is to keep your factory running until you manage to make \$10,000 (in total, combining the value of stock in hand plus your capital). You have to deal with recalcitrant unions (who won't always let you fire the people you wish to get rid of, and have a great appetite for pay rises which you cannot deny), with workers who will hardly ever meet the production targets you set, and raw material suppliers who enjoy putting their prices up as much as the unions enjoy slugging you for more pay.

You'll find, in contrast to the other two programs which are only very vague approximations to 'real life' that the life and health of your factory will become very important to you, and you'll certainly learn ways of manipulating resources for maximum return. Keep in mind that although you have great freedom in setting the retail price of your products, each rise in price will increase consumer resistance to purchasing those products.

Here are a few samples from a run of CHAIRMAN OF THE BOARD:

Shop floor report, sir,
for week 1

Capital in hand is \$ 520
Running costs are \$ 119 a week

Your stores hold 414 kazoos
worth \$ 4968

They sell for \$ 12 each
and cost \$ 10 each to make

Your workforce is now
10 strong, and you are
paying them \$ 12 each, so
the wages bill this week is \$ 120

Each person can make 10
kazoos a week, a total
output of 100
How many people do you
want to hire? 3

Your workforce is now
13 strong, and you are
paying them \$ 12 each, so
the wages bill this week is \$ 156

Each person can make 10
kazoos a week, a total
output of 130
How many do you wish to produce? 130

You do not have enough money
How many do you wish to produce? 100

You do not have enough money
How many do you wish to produce? 70

You do not have enough money
How many do you wish to produce? 20

Yes sir...the target for week 1
is 20 kazoos

The number of kazoos
actually produced in week 1
was 19 ...

The total number of kazoos
sold is 340

The income from that
sale was \$ 4080

A fire in your warehouse has
destroyed some stock. Please
stand by for a report on
the damage caused...

There were 33 kazoos
destroyed. They were
worth \$ 396 retail

You have a chance to raise
your price. Your
kazoos now sell for \$ 12

What percentage increase would
you like to impose? 7

The kazoos now sell for \$ 12.84

How many people do you
wish to fire? 7

The unions will allow
you to get rid of 3

The unions are demanding a
pay rise of 4 %

Pay per employee is now \$ 12.48

You're bankrupt!!

Oh the shame of it!!

Still, you keep the business
going for 6 weeks

Enter 'Y' for another stint
as Chairman of the Board...
(or 'N' if you want to quit)

And now you can satisfy your
corporate ambitions with this listing:

Dice Games

Dice Games

Dice games -- for high stakes, low stakes or none -- have proved popular throughout history. Whether the dice were made from stone or wood, or carved from the bones of a beast killed for food, whether they had four important sides or six, dice have proved a diversion for countless men throughout time.

The dice, physical means of demonstrating the waywardness of chance, have also found employment in fortelling the future, and like all oracles, probably bear some responsibility for changing the tide of history.

At Troy the Greeks played with dice, as did Mark Antony at Alexandria. Italy and France led medieval Europe in its love for dice, and devotion to the six-sided cubes has continued up to the present day. In this section of the book, we'll be investigating ways of using the random number generator of your computer to take the place of physical dice. However, you'll discover that the dice are no less compelling because they exist only within the software of your computer rather than in a more gross physical form.

Playing against the computer, instead of against another human being, changes the 'feel' of dice games somewhat. Not having to pay up when you lose is one of the real advantages!

An enormous range of games is now played with dice, and they sport an intriguing variety of titles. Here are some names of common dice programs:

- Going to Boston
- Craps
- Fifty
- Crag

- Pig
- Chicago
- Twenty-Six
- Twenty-One
- Round the Clock
- Centennial
- Yankee Grab
- Help Your Neighbour
- Drop Dead
- Shut the Box
- Baseball
- Basketball
- Poker Dice
- Liar Dice

The dice games we'll be playing in this book are SNAKES EYES, ONE-AND-TWENTY, SEVEN/ELEVEN, OVER'N'UNDER, NO SWEAT and CHEMIN DE COMPUTER.

CHEMIN DE COMPUTER

CHEMIN DE COMPUTER is based, as I'm sure you've realised, on Chemin de Fer. In this game, you and your computer take it in turns to roll five dice, adding the pips up as you go. You are aiming to get a higher total than the computer.

However, this game is not just a simple 'add the pips' one. Any die which falls showing a five or a two must be thrown again, and your total is just the final digit of the answer (that is, a total of 27 is counted as 7, and a total of 13 is counted as 3).

There are three special totals - 7 (a Natural), 8 (La Petite) and 9 (La Grande). The names are only bestowed when the relevant total is achieved on the first throw (i.e. the dice which came up with 5 or 2 have not been, and are not in this case, rethrown). You (and the computer) always stand on a 7, 8 or 9 thrown with the first toss of the five dice.

If you look at the program listing, you'll see that after the random number generator has been seeded in line 20, the screen cleared and the game counter (GAME) and variables for your score (HS) and that of the computer (CS) have been initialised to zero, the program goes to line 330, where the game proper begins.

As in many other programs in this book, there is a delay loop routine at the end of the listing which is called a number of times throughout a game to improve the speed with which the game advances, and to give you (in many cases) a chance to read on the screen what is going on before the program races on, clearing the screen, and leaving you quite unsure of exactly what has just happened. In this program,

there are two loops, one which is longer than the other, and which also prints a couple of blank lines before returning to the main program.

Line 330 calls a delay and then clears the screen before incrementing the counter GAME in the next line. You are told which game it is by line 350 and then the computer announces that, because it is taking the role of the banker, who always goes first, it will take the first role. The 'roll the dice' subroutine from line 70 is then triggered. You'll see that the loop counter G is used (line 80) to set the variable A to a randomly chosen value between one and six each time through the loop. If the die comes up with five or two (line 90) then it is reset to zero, before the value is printed by the following line.

The running total is clocked up on variable D, and then leading digits are stripped from this (i.e. 27 is cut down first to 17, then to 7) by line 150. The changing total is printed on the screen each time. After a delay the computer prints up "Total on the first roll is..." and then checks (lines 180, 190 and 200) to see if one of the special rolls has eventuated.

If so, a message to that effect is printed. If not, the computer gets to line 210 where it can see if any dice have to be rolled again (C is incremented by one each time a 2 or a 5 is rolled, see line 90). If there are none which have to be re-rolled, the computer moves on to line 410 to print out "So my final total is...". If, however, C is not equal to zero, then the computer runs through another loop (240 to 300) to throw those dice again. Once again, any dice coming up tw or five is discarded (line 280).

Once the computer has had its roll, it is your turn to play. Your involvement, actually, is pretty small at this stage. Once you've pressed RETURN (lines 440 and 450) the computer takes over for you,

using the same routine near the beginning of the program to roll the dice for you, and incrementing your total as it does so.

Once both of you have had your go, the computer then decides if it has beaten you, or you have defeated it, or whether the two of you have drawn ('Standoff'). The aim of Chemin de Computer is to win the majority out of nine scoring games (and a Standoff game does not count as a scoring game).

"Now the totals so far in Chemin de Computer are..." you are told by line 670 and -- if nine scoring games have not been played -- the computer makes some comment on the game ("Looks like I'm in front..." or "And you seem to have the edge...") before returning to the main program.

Once a total of nine scoring games has been detected (by line 700) then the routine from line 750 comes into action. "Well, old buddy, we seem to have come to the end of the game..." the computer tells you, then determines who has been the overall winner.

You're in good company when you play this game. Baccarat, from which Chemin de Fer was derived, was first introduced into France from Italy in about 1490, during the reign of Charles VIII. The Italian game was called 'Baccara'.

Here's what it looks like in action:

>>>> This is game 3 <<<<

Now, I'll roll as banker...

5 6 2 5 4

10

0

Total on the first roll is 0

3 must be rolled again

6 2 1

So my final total is 7

Press RETURN to roll your dice

5 1 5 2 1

2

Total on the first roll is 2

3 must be rolled again

1 2 6

So your final total is 9

Computer Human

7

9

\$

You're the winner that time!

\$

3 must be rolled again

1 2 6

So your final total is 9

Computer

Human

7

9

\$

You're the winner that time!

\$

Now the totals so far in

Chemin de Computer are

1 for me, and 2 for you...

And you seem to have the edge!

Now the totals so far in

Chemin de Computer are

4 for me, and 5 for you...

Well, old buddy, we seem

to have come to the end

of the game...with a total

of nine scoring rounds...

And, for once, it is

you who has beaten me!

Thanks for the game, old

buddy, we must do it again

some time, when you feel

lucky.....

And here is the program listing:

SEVEN/ELEVEN

SEVEN/ELEVEN is another fine dice game, and one in which your goal changes in each game. Based on CRAPS, you have a 'target number' to reach in each round (known as your 'point' in Craps).

Craps is an American version of the old English dice game Hazard. In SEVEN/ELEVEN, the complex betting of craps has been removed, leaving just the fun of the game. Rather than worry about computing odds and placing 'pass' and 'don't pass' bets, you can concentrate on the serious business of praying for the right roll to come up.

In this game, you are playing against yourself. Your winning and losing rounds are tallied, so you know -- at every point in the game -- just how well (or otherwise) you are doing.

You throw two dice at a time. If you throw a 2, 3 or a 12 with your first roll, you lose that round. Getting a 7, or an 11, on the first roll is the best thing you can do, because you've won that round with that single roll (which is why the game is called SEVEN/ELEVEN).

Any other number rolled as your first roll of a round becomes your 'target number'. You have to try and roll this again, before you roll a 7 or an 11. If you manage to roll your target number again, you win that round. However, rolling a 7 or an 11 before you've rethrown your target total, causes you to lose that round.

Here are some 'snapshots' of the game in progress:

The tally so far:
Wins: 1 Losses: 1
You have \$ 105

This is round number 4

Press 'R' to roll
You rolled 5
and 3

In 7/11 you've rolled 8

Your target number is 8

Press 'R' to roll
You rolled 6
and 1

In 7/11 you've rolled 7
And so you lose

The tally so far:
Wins: 1 Losses: 2
You have \$ 100

This is round number 5

Press 'R' to roll

And this is the listing of SEVEN/ELEVEN:

```
10 REM Seven Eleven
20 B$ = "In 7/11 you've rolled"
30 G = 0:W = 0:L = 0:M = 105
40 CLS
50 PRINT:PRINT "The tally so far:"
60 PRINT "Wins:"W"    Losses:"L
70 G = G + 1
80 M = M - 5
90 PRINT "You have $"M
100 PRINT:PRINT "This is round number"G
110 GOSUB 200
120 IF A = 7 OR A = 11 THEN 300
130 IF A = 2 OR A = 3 OR A = 12 THEN PRI
NT "so that's the end of the round":GOTO
320
140 P = A
150 CLS:PRINT:PRINT "Your target number
is"P
160 GOSUB 200
170 IF A = P THEN 300
180 IF A = 7 OR A = 11 THEN 310
190 GOSUB 340:GOTO 150
200 N = 0
210 PRINT:PRINT"Press 'R' to roll"
220 N = N + W: IF INKEY$ = " " THEN 220
230 C = INT(RND*6) + 1:PRINT "You rolled

310 PRINT "And so you lose":L = L + 1
320 GOSUB 340
330 GOTO 40
340 FOR T = 1 TO 500: NEXT T
350 RETURN
```

NO SWEAT

The name of this game -- NO SWEAT -- comes from one of the the early English names for the game from which this is derived. Known as 'Sweatcloth', the game, when first played in England, used three dice within a wooden 'shoe'. The most common variation of this game is now seen in US gambling casinos where it is called 'Birdcage', because of the equipment which is used.

In Birdcage, three dice are held within a metal cage which can spin about a central axis. Once bets have been laid, the cage is rotated. This is supposed to ensure that the dice are spun properly, as they are not actually touched by a casino operator.

Betting in Birdcage, and in No Sweat, is fast and simple, and despite the fact that you might think the odds are in your favor as a player, you'll quickly learn how easy it is to lose your shirt.

You place a bet of a specified amount (see lines 50 and 60) up to the size of your stake (held by the variable M, for money - see lines 30 and 250) and then chose a number between one and six. The amount of your bet is subtracted from your stake, and then the three dice are rolled. For each one which lands showing your number, you'll have an amount equal to your bet returned to you.

As you can see, this means you have to throw one die with your number showing to break even, and two to actually make some money. The need to throw the same, chosen, number twice is what gives the casino such a good edge in this game.

After the random number generator is seeded in line 20, and the money variable (M) is set to 30 for you

in line 30, the computer goes to the subroutine from line 240 which prints up:

Your stake is now \$30

After this, the game gets underway.

Line 50 asks you how much you'd like to bet, and the variable A is assigned to your choice. This is compared with the money you actually have (in line 60) to see if you are trying to bet more than you have on hand. Having past that hurdle, your bet is subtracted from your stake in line 70 and then the computer asks you (line 50) to enter your bet.

The C loop, from lines 100 to 180 rolls the dice, and compares each roll with your number, reporting to you after each roll. Your winnings (if there are any) are also added in this loop.

After each round of the game, your money (M) is compared with 250 (if you've got more than \$250 you've exceeded the house limits are are therefore excluded from future play) and with zero (those who have no money are not allowed to play further). If, however, you do not have more than 250 nor less than zero, you're able to continue playing.

Here's NO SWEAT in full play:

Your stake is now \$ 30

How much would you like to bet? 4

Which number are you betting on? 5

Die 1 fell 4

Your stake is now \$ 26

```

Die 2 fell 5
so you win $ 4
*****
Your stake is now $ 30
*****

```

```

Die 3 fell 2
*****
Your stake is now $ 30
*****

```

```

Your stake is now $ 5
*****
How much would you like to bet? 4

```

Which number are you betting on? 6

```

Die 1 fell 6
so you win $ 4
*****
Your stake is now $ 5
*****

```

```

320 PRINT "You've topped $250!"
330 PRINT TAB(J);"Well done!!"
340 NEXT J

```

ONE-AND-TWENTY

Our dice games continue now with ONE-AND-TWENTY which, as you realised the moment you read the title in the introduction, is a dice version of the card game, Pontoon.

The game is simple, but demands a degree of cool thinking, as well as the ability to guess which numbers are going to come up next when the die is rolled. In ONE-AND-TWENTY, you are playing against the computer.

You are always given the first go. You roll the die as many times as you like, aiming to get a total as close as possible to, but not exceeding, 21. You can stop adding to the total whenever you like.

If you exceed 21 (that is, you 'bust') then the computer wins that round automatically. A game consists of five rounds, and the winner of the most rounds, naturally enough, wins the game.

After initialising some variables (including HS for the human score and CS for the computer score) in lines 20 and 30, and clearing the screen in line 40, the computer asks you to "Press 'R' to roll, 'S' to stand". The word 'Stand' means you are happy with the total you've achieved so far and you'll stay with it, giving the computer a chance to try and beat you. You'll soon learn that the speed with which you enter an R or an S can effect the number which is thrown, because the delay between the "Press 'R' to roll..." and the time you actually do press an R or an S is used to create a number (N) which -- together with your current total -- is used to seed the random number generator for the next dice roll.

The lines from 50 to 170 control your dice-rolling, and the computer only exits this cycle when you decide to stand. The whole of the computer's game-playing logic is held within line 180 which determines whether it is worth risking a bust to try and exceed your total. If it decides to roll, the lines from 190 to 250 control this.

Once the computer decides it has had enough of that, it uses lines 260, 280 and 290 to determine who has won. If both your scores are the same, or both of you are over 21, then the round is counted as a dead heat (line 320 tells you this), and neither CS nor HS is incremented. Line 280 spots a computer win, adding one to CS and printing "I", while the next line adds one to HS and prints "You". The mysterious "I" and "You" are used as the first part of the sentence concluded by "win!!!" in line 300.

As in Chemin de Computer, where the aim was to get the best out of nine scoring games, in One-and-Twenty, the intention is to score wins in the majority of games out of five. Line 390 looks to see if this has happened, and if so sends the program to line 450 where the result of the game (with a sarcastic comment or two) is printed. If five scoring games have not been played, line 400 asks you to "Stand by for the next round.." and after a brief pause (line 430), the next round is upon you.

Let's have a look at part of a game in action:

Your total is 18

I rolled a 4
so my total is 4

I rolled a 4
so my total is 8

I rolled a 4
so my total is 12

I rolled a 5
so my total is 17

I rolled a 2
so my total is 19

I win!!

I rolled a 6
so my total is 22

You win!!

After that round, the game score is
You: 2 , and me 3

That's the end of the game

Final scores:

You: 2
Me: 3

And I defeated you, humanoid!

This listing will enable your computer to challenge (and probably beat you) in ONE-AND-TWENTY:

```

10 REM One-and-Twenty

SNAKES EYES

SNAKES EYES demands some more cool thinking under pressure. You and your computer take it in turns to throw a pair of dice. You add the total of the pips, and in turn add this to your score.

You can roll the dice as many times as you like, but if you roll a seven, you automatically lose. Therefore, as you can see, the program demands you make decisions based on whether you should be careful and perhaps lose the round by not rolling a high enough score, or whether you should be greedy and go for the absolute maximum score and risk a seven.

As in ONE-AND-TWENTY, the time you take to press RETURN to roll the dice, has some effect on the score you achieve. You can see, in lines 120 to 150, that the variable N (set to zero in line 120) is incremented by one each time around the 140/150 loop, until you press the "q", "Q", "r" or "R" keys.

If you press "r" or "R" to indicate that you wish to roll the dice, the computer goes to the subroutine from line 370 where the screen is cleared (380) and then the two dice (X and Y) are rolled. The Q loop is covered 20 times, gradually slowing down as it is traversed (by the inner loop, in line 430), until finally -- with line 420 -- the results of the dice rolls are printed. The variable Z is set equal to the tally of the two rolls (in line 480) before the computer goes to line 700 for the delay and to print a line across the screen, and then returns to the start of the program to line 180, the one after the one which sent it to the 'roll the dice' routine. Here the computer checks that the total is not 7 (line 180) and if it is not, then adds the result of the latest roll to your tally.

If, however, you signal through INKEY\$ that you wish to quit, the action goes to the routine from line 220. After printing STAND BY, the computer goes to the delay loop, and line print routine, and then uses the same routine as the human did for rolling the dice, and -- on returning from the subroutine -- checking that the total was not 7, and if not, adding the new total to the score. The computer has a very simple means of deciding if it will roll again...if it has less than the human, it takes the risk.

You'll find that it is relatively easy to program games like this on your computer. Once you've worked out the 'mechanical routines' which do such things as roll the dice, and increment the score, for the human player, it is not very difficult to work out a routine to enable the computer to use the same mechanical routines. Most dice games do not demand much 'intelligence' and their strategy can often be reduced to a couple of IF/THEN statements. Read books on dice games -- such as the excellent DICE GAMES OLD AND NEW by William E Tredd (The Oleander Press, New York, 1981) -- to get ideas for games to turn into programs, and for simple ideas on how to play the game as well as possible. It is these ideas which you should find relatively easy to turn into simple 'intelligent algorithms' to enable your computer to play reasonably well against you.

And, if as in this case and in ONE-AND-TWENTY, you stipulate that the human must go first, the computer knows exactly what target it is aiming at, and therefore starts a round with a considerable advantage, which helps overcome the machine's inherent stupidity.

Anyway, here's what SNAKES EYES
looks like when it is up and running:

Please stand by...

Your total is 0

Press 'R' to roll
'Q' to quit

Die one: 1 Die two: 2

Your total is 3

Your total is 3

Press 'R' to roll
'Q' to quit

Die one: 4 Die two: 4

Your total is 11

Your total is 11

Press 'R' to roll
'Q' to quit

Die one: 6 Die two: 6

Your total is 23

Your total is 23

Press 'R' to roll
'Q' to quit

Stand by

Die one: 5 Die two: 5

My total is 10
Your total is 23

Stand by

Die one: 4 Die two: 1

My total is 15
Your total is 23

Stand by

Die one: 2 Die two: 1

My total is 18
Your total is 23

Stand by

Die one: 4 Die two: 2

My total is 24
Your total is 23

I win!

The score is:

You: 0
Me: 1

And I'm in the lead...
Please stand by...

Your total is 0

Press 'R' to roll
'Q' to quit

Die one: 1 Die two: 3

Your total is 4

Your total is 4

Press 'R' to roll
'Q' to quit

Die one: 3 Die two: 5

Your total is 12

Your total is 12

Press 'R' to roll
'Q' to quit

Stand by

Die one: 5 Die two: 2
You win!

The score is:

 You: 1
 Me: 1

The score is:

 You: 1
 Me: 7

And I'm in the lead...
Please stand by...

Your total is 0

Press 'R' to roll
'Q' to quit

Die one: 6 Die two: 2

Your total is 8

Your total is 8

Press 'R' to roll
'Q' to quit

Die one: 4 Die two: 3
I win!

The score is:

 You: 1
 Me: 8

Well, buddy, that's the end
of the game...

Your final score was 1
and mine was 8
I'm the winner!!

And this is the listing for the game:

```

```

UNDER 'N' OVER

UNDER'N'OVER is a computer adaptation of the dice game usually known as 'Under and Over Seven'. In this game, you bet on the likelihood of the total of a pair of dice landing so that the total is:

- less than seven;
- exactly equal to seven; or
- greater than seven

Again, this is a game which -- at first sight -- seems to offer pretty good odds to the player. However, if you played the game forever, with a pair of perfect dice, you'd find your losses would outweigh your wins by nearly 17%.

The program structure is not hard to follow. After seeding the random number generator in line 20 and clearing the screen in line 30, the computer sets your starting stake (again called M for money) to 30 (for \$30). Line 50 sends action to the subroutine from line 450 where your current money is printed up: "You now have \$30" before returning to line 60 where the delay subroutine (lines 470, 480 and 490) is called.

Lines 70 to 120 ask you to place your bet, giving you the key for entering it (press A to bet under seven, B to bet on seven and C to bet on a total greater than seven). Lines 130 and 140 read the keyboard using INKEY\$, rejecting (line 140) any input which is not A, B or C.

Having received a valid choice, the odds are printed up by lines 150 to 180 and then line 200 asks you to

enter the amount of your bet. Of course, you can't bet more than you have (not in this game, anyway) so line 220 checks your bet (A) against your money (M) and if you haven't got enough prints up: "You haven't got that much!".

The next section rolls the dice, assigning random values between one and six to variables B and C, and adding them to produce total D in line 280. You are told of the total by line 300.

THE OUTCOME

This is determined by the routine from lines 310 to 350 where a loss is first assumed (line 310, with variable W, for 'win', assigned to the negative of your bet). This is changed -- if needed -- into the correct amount for a win if one has, in fact, taken place. You can see you get paid four times your bet for correctly specifying the dice will land with a total of seven (line 320) and even money for either over or under seven (lines 330 and 340).

Lines 370 and 380 tell you about your win (or loss) and then lines 420 checks that you still have some money in hand. If you have, you are offered a new round of the game. If not, you are dismissed with a certain severity.

Here's UNDER'N'OVER in action:

OK, punter, 'tis time to
place your bet.....

Enter 'A' to bet under 7
 'B' to bet on 7, or
 'C' to bet over 7

The odds are:

A - pays even
B - pays 4 to 1
C - pays even

Now how much would you like to bet? 625

Die one came up 1

Die two came up 6

So the total is 7

You've just won \$ 2500

Enter 'A' to bet under 7
 'B' to bet on 7, or
 'C' to bet over 7

The odds are:

A - pays even

So the total is 6

And so you lose \$ 15625

You now have \$ 0

You're flat broke, buddy
so I gotta close the casino

There's no room for deadbeats in my joint

And this is the listing to turn your
computer into a dice fiend:

```
10 REM Under'n'over

Artificial Intelligence

Artificial Intelligence

Artificial intelligence is a goal which has not yet been achieved. Certainly, programs which enable computers to exhibit behavior which could conceivably be classed as intelligent have been written, but the 'intelligence' has been limited and effective only within a severely restricted domain. That is, a computer can appear to be brainy, but only if you limit the environment within which it has to demonstrate those brains.

In this section of the book, we have four programs which will give your computer the appearance of intelligence, and certainly provide impressive demonstrations of 'electronic brainpower' when the programs are shown to computer-naive people.

Despite the claims made by some people (such as Carl Sagan, "In Defense of Robots", Broca's Brains) that human beings are, essentially, just well-made computers, we sense there is a wide gulf between our own perception of our selfhood, and the total non-awareness that computers can have (at least at present) of their own existence. And it seems to me that this self-perception lies at the heart of at least one aspect of intelligence.

Computers can function extremely 'intelligently' in restricted areas. Look at the five inch square, hand-held chess machines. Within the limited domain of chess game, a solid appearance of intelligence can be created.

It is so within the limited universes created by the programs in this section. One of them is a variant of one of the most well-known and popular AI programs ever, ELIZA, in which the computer takes the role of a psychiatrist, and apparently carries on a conversation. ELIZA was developed in the mid-60s by Joseph Weizenbaum. He was attempting to produce a program which would caricature a Rogerian

psychoanalyst, and it has been suggested (see "You're never alone with a fluffy micro", David Tebbutt, MicroScope, January 13 1983, p. 9) that Weizenbaum has regretted ever since that day his work on Eliza. It is not hard to see why.

In the euphoric days after the program was made public, wild and erratic claims were made that it was only a matter of (very little) time before computers could totally replace 'mind-doctors'. Further, the Eliza success -- said some incautious observers -- paved the way for genuinely intelligent computers.

Weizenbaum did not believe it for a moment. He writes that he was amazed at the beginning -- and continued to be amazed -- at the reaction people had to the program. Written in LISP on a mainframe at MIT, the program could be accessed from anyone of a number of time-sharing terminals dotted around the campus. Weizenbaum reports he was very interested to see that the program was being accessed time and time again very late at night, as though troubled students were really discussing their problems with the program. Furthermore, the accesses were all very long. The computer log showed some people were hooked into Eliza for over an hour at a time.

Weizenbaum's secretary had worked closely with him over the six months or so it took to produce the program, and she knew as well as he how it worked, scanning a person's speech for 'key words' (such as dream and friends) and then choosing a suitable reply from a bank of such replies. Other words from the user's sentences could be incorporated, sentences could be 'turned around' (so "I am happy because of the weather" could be simply fed back as either "Why are you happy because of the weather" or just as a statement of the form "You are happy because of the weather. What does this suggest to you?") and a number of other replies (such as "That is interesting, please go on") could be used if no keyword was recognized.

Despite the secretary's familiarity with the program, Weizenbaum noticed that if he walked into the office when she was accessing the program, she became embarrassed and refused to let him see the print out. Further, when he suggested it would be interesting to hook up a printer to the main body of the computer to record the late night conversations students had with the program, the suggestion was greeted with horror, as though he was suggesting a kind of electronic peeping-Tom activity. (If you'd like to look further into Weizenbaum's work on AI, you might be interested in his book Computer Power and Human Reason, W H Freeman and Co., San Francisco, 1976.)

A common stumbling block in the work of early researchers into the field of artificial intelligence was that writing a program which emulated some aspect of human reasoning (such as a very impressive Checkers program by Samuels) did not necessarily lead researchers any closer to either producing behavior which could be classed as intelligent, nor towards a theoretical understanding of the processes of human reasoning and deduction. "Progress in producing intelligent behavior is not necessarily progress towards producing thought" (Norman Whaland, When Is A Program Intelligent?, Creative Computing, February 1981, pp. 44 - 49).

There is another way of approaching the problem, which I call the "if it quacks like a duck, it's a duck" approach. In the book "The Turing Criterion - Machine Intelligent Programs for the 16K ZX81" (Charlton et al, Interface Publications London, 1982), which I edited, I answer the question "What is the Turing Criterion?" in the following words:

"In 1950, the English mathematician and logician A. M. Turing proposed what has become known as the 'Turing Criterion' for machine intelligence.

"He said that if you were dealing with something at the end of a wire that could be a

machine, or could be human, and you could not tell -- from the responses coming to you over the wire -- whether that with which you were dealing was human or machine, the 'thing' at the other end was, by definition, intelligent.

On this basis, it would be possible to class many, many computer programs as intelligent. Certainly those within this section of the book could almost pass the test, especially if you were prepared to accept the possibility that some pretty stupid humans were dealing with you.

Time now to explore the worlds of Artificial Intelligence with the following programs:

- * Eliza
- * Electronic Brain (in which the computer tries to crack a 'mastermind-like' code you've worked out)
- * Proboscidean (from the adjective describing the class of mammal elephants belong to, in which you face the computer in a round of 'Concentration')
- * Amanuensis (in which the computer accepts the task of writing poetry)

ELIZA

We'll start our investigation of Artificial Intelligence with a simplified version of the classic program, ELIZA, which we discussed at some length in the introduction. As we said there, the program scans your input for words it can use, and then reflects your words back to you in a way which makes it seem as if the program is really speaking to you. Once you've played with it a while, you'll learn how to trigger the most effective responses.

Here's part of one 'conversation' I had with my version of ELIZA:

WELCOME TO ANOTHER SESSION WITH
YOUR COMPUTER PSYCHIATRIST, ELIZA

WHAT IS YOUR FIRST NAME? TIM

WELL, HI THERE TIM

IT SURE IS NEAT TO HAVE YOU DROP BY

PRESS MY SPACE BAR WHEN YOU'RE READY TO START

? I HAVE A SERIOUS PROBLEM
WHY ARE YOU SAYING THAT?

? BECAUSE I'VE COME TO YOU FOR HELP
TIM, I'M NOT SURE I UNDERSTAND YOU FULLY.

? I AM AFRAID OF MICE
TIM, HOW LONG HAVE YOU BEEN AFRAID OF MICE

? SINCE BEFORE I TOOK UP COMPUTERS
TIM, WHY DO YOU MENTION COMPUTERS?

? IT SEEMED RELEVANT AT THE TIME
THAT IS QUITE INTERESTING!

? AS I WAS SAYING I AM AFRAID OF LITTLE SQUEAKY THINGS
HOW LONG HAVE YOU BEEN AFRAID OF LITTLE SQUEAKY THINGS

? I THINK WE HAVE BEEN THROUGH THIS BEFORE
DO YOU DOUBT WE HAVE BEEN THROUGH THIS BEFORE

? I SOMETIMES DOUBT EVERYTHING
TIM, WELL, WELL...DO GO ON.

? MANY PEOPLE HAVE DOUBTS
WELL, WELL...DO GO ON.

? I BET EVEN YOU HAVE DOUBTS
THAT'S SO...PLEASE CONTINUE...

? DO YOU EVER DREAM OF ROBOTS
YES, I EVER DREAM OF ROBOTS

? WELL I NEVER EVER DREAM ABOUT THEM
WHY DID YOU BRING UP THE SUBJECT OF DREAMS?

? I HAVE THIS THING ABOUT MICE
COULD YOU SAY THAT AGAIN, IN A DIFFERENT WAY?

? I'M AFRAID THEY'LL COME AND JUST STAY FOR TEA
TIM, WHY ARE YOU TELLING ME YOU'RE AFRAID
THEY'LL COME AND JUST STAY FOR TEA

? I THOUGHT YOU WERE MEANT TO ASSIST IN AN
HOUR OF NEED
CAN YOU ELABORATE ON THAT?

? HOW CAN I SAY IT MORE CLEARLY
PERHAPS YOU DON'T WANT TO BE ABLE TO SAY IT
MORE CLEARLY

? I THINK YOU ARE A FRAUD
WHAT MAKES YOU THINK I AM A FRAUD

? BECAUSE YOU NEVER GIVE ME A STRAIGHT ANSWER
I'M NOT SURE I UNDERSTAND YOU FULLY.

? COME ON TURKEY I WANT A STRAIGHT ANSWER
TIM, WHY DO YOU WANT A STRAIGHT ANSWER

? TO HELP ME IN MY HOUR OF NEED
TIM, I SEE...

? YOU'RE PRETTY DUMB FOR A MACHINE
WHAT IS YOUR REACTION TO ME BEING PRETTY
DUMB FOR A MACHINE

? IT MAKES ME WANT TO DRINK HEAVILY
MODERATION IN ALL THINGS SHOULD BE THE RULE.

? EVEN IN SEX
I FEEL YOU SHOULD REALLY DISCUSS THIS WITH A HUMAN.

? BYE
BYE BYE FOR NOW.
SEE YOU AGAIN SOME TIME.

And here's the listing, so your computer can now
help you sort yourself out:

ELECTRONIC BRAIN

ELECTRONIC BRAIN is an attempt to write a program which would work towards the answer to a problem, in an apparently intelligent manner. The computer is attempting to solve a problem of the type where you think of a numerical code, and the computer tries to guess it. The feedback you give its answers are as 'whites' and 'blacks', where a white is given for a digit which is correct, but is in the wrong position in the code, and a black is given whenever there is a correct digit within the code.

The problem is not totally straightforward, as the computer does not know, for certain, which digit produced which result. I wrote two versions of this program, one to solve three-digit codes, and a modification of that program to solve four-digit ones. It works in a simple manner (although implementing the relatively simple idea behind the program was not particularly easy). Everytime a digit appears in a code which is awarded a black, every digit within that code is weighted so that it appears more often in future guesses. The more blacks in that particular code, the higher the weighting each code gets. A much smaller weighting is awarded if the code gets one or more whites. Any code getting neither a black nor a white leads to all the digits within that guess being totally removed from future consideration.

As I said, the three-digit version is the basic upon which the four-digit program was written. Enter the three-digit one first, and then save it in that form, before making the needed conversion to make it work as a four-digit program. Whereas the three-digit version works reasonably well, and reasonably quickly, the four-digit program grinds almost to a halt towards the end, as it tries to generate codes

which (a) reflect the weighting that previous answers have produced, and (b) are not codes which have been previously suggested in that particular run.

Here's the program solving a three-digit code:

Guess number 1

My guess is 1 2 3

How many blacks? 1

And how many whites? 0

Guess number 2

My guess is 4 5 6

How many blacks? 0

And how many whites? 1

Guess number 3

My guess is 7 8 9

How many blacks? 1

And how many whites? 0

Guess number 4

My guess is 4 2 6

How many blacks? 0

And how many whites? 1

Guess number 5

My guess is 8 2 1

How many blacks? 0

And how many whites? 1

Guess number 6

My guess is 1 9 4

How many blacks? 1

And how many whites? 2

Guess number 7

My guess is 1 4 9

How many blacks? 3

I guessed your code of 1 4 9
in just 7 guesses

And this is the listing that produced it:

```
10 REM ELECTRONIC BRAIN - 3 digits
20 GOSUB 510:REM INITIALISE
30 REM MAKE A GUESS
40 IF GUESS < 3 THEN FOR Z = 1 TO 3:B(Z) =
Z + 3*GUESS:NEXT Z:GOTO 70
60 GOSUB 280
70 CLS
80 GUESS = GUESS + 1
90 PRINT:PRINT
100 PRINT "Guess number"GUESS
110 PRINT
120 PRINT "My guess is"B(1);B(2);B(3)
130 PRINT:PRINT
140 INPUT "How many blacks";B
150 IF B = 3 THEN GOTO 600
160 IF B = 2 THEN 190
170 PRINT:PRINT
180 INPUT "And how many whites";W
190 IF W + B = 3 THEN Q = 3:C(1) = B(1):C(2)
) = B(2):C(3) = B(3)
200 IF B + W = 0 THEN C(B(1)) = 0:C(B(2)) =
0:C(B(3)) = 0:GOTO 30
210 IF B > AID THEN FOR Z = 1 TO 3:E(Z) = B
(Z):NEXT Z:AID = B
220 FOR Z = 1 TO 9
230 FOR D = 1 TO 3
240 IF B(D) = C(Z) THEN C(Z) = C(Z) + (B +
W)*100 + W*10
```

```
250 NEXT D
260 NEXT Z
270 GOTO 30
280 REM Pick three numbers
290 FOR Z = 1 TO 3
300 D1 = C(INT(RND*Q) + 1)
310 IF D1 = 0 THEN 300
320 D2 = C(INT(RND*Q) + 1)
330 IF D2 = 0 THEN 320
340 IF INT(D1/10) > INT(D2/10) THEN B(Z) =
D1
350 IF INT(D1/10) < INT(D2/10) THEN B(Z) =
D2
360 IF INT(D1/10) = INT(D2/10) THEN B(Z) =
D1
370 IF B(Z) > 100 THEN B(Z) = B(Z) - 100*IN
T(B(Z)/100):GOTO 370
380 IF B(Z) > 10 THEN B(Z) = B(Z) - 10*INT(
B(Z)/10):GOTO 380
390 NEXT Z
400 IF B(1) = B(2) OR B(1) = B(3) OR B(2) =
B(3) THEN 290
410 IF AID > 0 THEN COUNT = 0:FOR Z = 1 TO
3:IF B(Z) = E(Z) THEN COUNT = COUNT + 1
420 IF AID > 0 THEN NEXT Z:IF COUNT < AID T
HEN 290
430 M = 100*B(1) + 10*B(2) + B(3)
440 K(GUESS) = M
450 IF GUESS < 3 THEN 500
460 COUNT = 1
470 COUNT = COUNT + 1
480 IF K(COUNT) = M THEN 290
490 IF COUNT < GUESS - 1 THEN 470
500 RETURN
510 REM INITIALISE
520 DEFINT A - Z
530 GUESS = 0:Q = 9:AID = 0
540 RANDOMIZE VAL(RIGHT$(TIME$,2))
550 DIM B(3),C(9),E(3),K(100)
```

```

560 FOR Z = 1 TO 9
570 C(Z) = Z
580 NEXT Z
590 RETURN
600 PRINT:PRINT
610 PRINT "I guessed your code of"B(1);B(2)
;B(3)
620 PRINT TAB(5);"in just"GUESS"guesses"
630 END

```

Now, after some conversion, the computer is trying to crack a four-digit code:

Guess number 10

My guess is 9 5 1 2
How many blacks? 0
And how many whites? 1

Guess number 13

My guess is 4 3 7 1
How many blacks? 1
And how many whites? 1

Guess number 11

My guess is 1 2 4 9
How many blacks? 0
And how many whites? 2

Guess number 14

My guess is 7 3 4 2
How many blacks? 1
And how many whites? 1

Guess number 12

My guess is 7 1 4 9
How many blacks? 0
And how many whites? 2

Guess number 15

My guess is 6 3 9 4
How many blacks? 4

I guessed your code of 6 3 9 4
in just 15 guesses

This is the listing to solve four-digit codes, which is based on the three-digit one. Note the addition of '- 1' in line 420 of this program, as well as the other changes:

```

10 REM ELECTRONIC BRAIN - 4 digits
20 GOSUB 510:REM INITIALISE

```

PROBOSCIDEAN

PROBOSCIDEAN is a program in which the computer shows what a wonderful memory it has, as it challenges you to a round of the card game 'Concentration'.

A deck of cards is shuffled, and then laid out on the screen. You and the computer take it in turns to choose two cards. These are turned over, and if they are a pair, the player who selected them is awarded a point. This process continues until all the cards have been selected. The winner, naturally enough, is the player who has selected the most pairs.

Here's a game in which (as usual) the mere human (me) is thrashed by the computer's 64K memory:

Please stand by, card-sharp!

Start flexing those memory muscles...

What level of difficulty (1 - 10)?
(10 is easy, 1 is almost IMPOSSIBLE!)
? 1

Your cards: 30 and 45

That's brings us to the end
of a round of Proboscidean!

I'm the winner, human!

You may well like to make the game easier, at least in the early stages, by adding a mechanism to remove guessed cards from the screen. This can be done by changing the third element of each string which represents a correctly chosen card. Here, though, is the listing which played that last game:

```

10 REM Proboscidean
20 GOSUB 790:REM Initialise/Shuffle
30 GOSUB 610:REM Print out
40 GOSUB 430:REM Human guess
50 GOSUB 150:REM Computer guess
60 IF HS + CS < 26 THEN 30
70 PRINT "That's brings us to the end"
80 PRINT "of a round of Proboscidean!"
90 PRINT
100 IF HS > CS THEN PRINT "You're the win
ner!"
110 IF CS > HS THEN PRINT "I'm the winner
, human!"
120 IF CS = HS THEN PRINT "It's a draw, h
umanoid!"
130 END
140 REM *****
150 REM Computer guess
160 MOVE = 0
170 IF R = 1 OR RND < LEVEL THEN 260
180 X = R
190 X = X - 1
200 Y = 1
210 Y = Y + 1
220 IF D(X) = D(Y) THEN 240
230 IF ASC(A$(D(X))) = ASC(A$(D(Y))) THEN
  IF X <> Y THEN IF MID$(A$(D(X)),3,1) = "
X" AND MID$(A$(D(Y)),3,1) = "X" THEN A =
D(X):B = D(Y):GOTO 340
240 IF Y < X THEN 210
250 IF X - 1 > R THEN 190
260 REM Random guess
270 COUNT = 0
280 COUNT = COUNT + 1

```

```

290 IF COUNT = 200 THEN 70
300 A = INT(RND*52) + 1
310 B = INT(RND*52) + 1
320 IF B = A THEN 310
330 IF RIGHT$(A$(A),1) <> "X" OR RIGHT$(A$(B),1) <> "X" THEN 280
340 PRINT "I've selected cards"A"and"B
350 FOR P = 1 TO 1000:NEXT P
360 MID$(A$(A),3,1) = " ":MID$(A$(B),3,1) = " "

AMANUENSIS

Next we'll have our poetry writing program. This demands no interaction from you, except for that of admiring the wonderful (!) output of the program. Here's a sample of the kind of verse it produces:

THE CONVOY CLAIMED SLAVISHLY
 IN THE COURT...
 PRAYING FOR AN ASTRAL INFLUENCE,
 TO DEMUR THE FAUN...
 EXHAUSTING, THEN GNAWING
 ...IMPOUNDING, BREAKING.

THE POSTULANT BESEECHED NEGLECTFULLY
 IN THE ENEMY'S CAMP...
 WANTING FOR A DOGMATIST,
 TO RECENT THE DJINN...
 DISPENSING WITH, THEN ERODING
 ...ENCLOSING, WOUNDING.

THE ASPIRANT CRAVED SUCCESSFULLY
 IN THE RACECOURSE...
 PRAYING FOR HOBSON'S CHOICE,
 TO QUENCH THE GHOST...
 EMPTYING, THEN BLIGHTING
 ...HANDCUFFING, ROTTING.

THE ASPIRANT ENTREATED HALTINGLY
 IN THE HIPPODROME...
 PRAYING FOR A BLIND BARGAIN,
 TO RECENT THE NAIAD...
 WASTING, THEN BREAKING
 ...RESTRAINING, UNDERMINING.

THE CASTELLAN DEMANDED HALTINGLY
 IN THE HIPPODROME...
 SCREAMING FOR THE FATES,
 TO RELINQUISH THE GHOST...
 EXHAUSTING, THEN DAMAGING
 ...SUPPRESSING, BREAKING.

THE APPLICANT PRESSED PRIDEFULLY
 IN THE ENEMY'S CAMP...
 WATCHING FOR A SPELLBINDER,
 TO DEMUR THE HOBGOBLIN...
 DRYING UP, THEN ROTTING
 ...HANDCUFFING, DAMAGING.

THE CLAIMANT CRAVED SLAVISHLY
 IN THE BEAR GARDEN...
 CRYING FOR HOBSON'S CHOICE,
 TO WAVER THE DRYAD...
 DRYING UP, THEN ERODING
 ...RESTRAINING, ROTTING.

THE MENDICANT CONJURED HELPLESSLY
 IN THE COURT...
 PRAYING FOR A DOGMATIST,
 TO QUENCH THE LEPRECHAUN...
 RUNNING OUT, THEN ERODING
 ...IMPOUNDING, BLIGHTING.

THE CONVOY DEMANDED HELPLESSLY
 IN THE HIPPODROME...
 WATCHING FOR A ZEALOT,
 TO ABJURE THE GHOST...
 SPENDING, THEN CORRODING
 ...IMPOUNDING, GNAWING.

THE POSTULANT ENTREATED ENDLESSLY
 IN THE PLAYGROUND...
 WAITING FOR HOBSON'S CHOICE,
 TO RELINQUISH THE SATUR...
 DISPENSING WITH, THEN DAMAGING
 ...COERCING, BREAKING.

THE BEGGAR CLAIMED HALTINGLY
 IN THE THEATRE OF WAR...
 ASKING FOR FORTUNE'S WHEEL,
 TO BACK THE NAIAD...
 DISPENSING WITH, THEN BREAKING
 ...MUZZLING, WOUNDING.

This is the listing of AMANUENSIS. Once you've run it for a while, you may well wish to change the words in the DATA statements, to vary the kind of poetry it produces.

Just for Fun

Just for Fun

Just for Fun

There is a range of games in this section of your book, all designed just for fun. From NOUGHTS AND CROSSES, through LAS VEGAS HIGH, to INNER SPRING and ROBOT MINEFIELD a splendid time is guaranteed for all.

As well as the games mentioned above, you'll find NIMGRAB and CADDY in this section. And if you have a group of little kids you'd like to leave playing with the computer for a while, we have a massive program called CAVALCADE OF PUZZLES, which brings together a collection of enjoyable games. You can only play one game when you've successfully completed the one before it. It's a great way of keeping the very young (in age or heart) amused.

Let's get down to it right away.

INNER SPRING

We'll start this section of the book with one of the simplest games of the lot, INNER SPRING. As the program explains, the computer produces two numbers between one and 13, and asks you to bet on the probability of the next number it thinks of lying between the first two. It's simple to play, and a lot of fun.

Here's what one round looks like in action:

MY FIRST NUMBER IS 2
MY SECOND IS 4

YOU HAVE \$ 2

HOW MUCH DO YOU BET
MY NEXT NUMBER LIES
BETWEEN 2 AND 4 ? 1

MY NUMBER WAS 3
WELL DONE, YOU WIN \$ 2

And here's the listing of INNER SPRING:

```
10 REM INNER SPRING
20 GOSUB 330
30 GOSUB 80
40 IF D<1 THEN GOTO 420
50 GOSUB 340
60 GOTO 30
70 REM *****
80 PRINT:PRINT:PRINT
90 PRINT "MY FIRST NUMBER IS"A
100 PRINT"      MY SECOND IS"B
110 PRINT
```

```
120 PRINT "YOU HAVE $"D
130 PRINT
140 PRINT "HOW MUCH DO YOU BET"
150 PRINT "MY NEXT NUMBER LIES"
160 PRINT "BETWEEN"A"AND"B;
170 INPUT E
180 IF E > D THEN 170
190 D = D - E
200 GOSUB 500
210 PRINT:PRINT "MY NUMBER WAS"C
220 GOSUB 500
230 IF NOT (C>A AND C<B OR C<A AND C>B)
THEN 290
240 PRINT "WELL DONE, YOU WIN $"2*E
250 D = D + 3*E
260 GOSUB 500
270 RETURN
280 REM *****
290 PRINT "SORRY, YOU LOSE $"E
300 GOSUB 500
310 RETURN
320 REM *****
330 D = 20
340 CLS
350 A = INT (RND*13) + 1
360 B = INT (RND*13) + 1
370 IF ABS(A - B) < 2 OR ABS(A - B) > 6
THEN 360
380 C = INT(RND*13) + 1
390 IF A = C OR B = C THEN 380
400 RETURN
410 REM *****
420 PRINT
430 PRINT "THE GAME IS OVER"
440 PRINT
450 PRINT "YOU ARE BROKE!"
460 PRINT
470 PRINT "THANKS FOR THE GAME"
480 END
490 REM *****
500 FOR Z = 1 TO 1000
510 NEXT Z
520 RETURN
```

NIMGRAB

NIMGRAB is a game which seems easy at first, but is the very devil to play...and win. You and the wily computer take it in turns to take objects away from the ones on the screen. There is a limit to how many you can take away each move (and this limit changes from game to game, although it does not change within a particular round of the game). The winner is the person who manages to force the other player to remove the last object.

Once you see it in action, you'll understand how to play it. Then you can start working on perfecting a method of actually beating the computer. Here is NIMGRAB underway:

The maximum you can grab is 4

#####

1
2 3
4
5 6 7
8 9 10
11 12 13 14 15 16 17 18 19

#####

How many will you grab?

So you want to grab 2

#####

#####

The maximum you can grab is 4

#####

You took 2 , and I took 2

1
2 3
4 5 6 7 8 9 10
11 12
13 14 15

#####

How many will you grab?

#####

The maximum you can grab is 4

#####

You took 1 , and I took 4

1
#####

How many will you grab?

So you want to grab 1

#####

You grabbed the last one
so I win!!

And here is the listing of that program:

```

10 REM Nimgrab
20 CLS
30 PRINT "Press 'S' to start the game..."
40 N = 0
50 N = N + 1: IF INKEY$ = "" THEN 50
60 RANDOMIZE N
70 CLS
80 M = 0:E = 0:Z = INT(RND*8) + 16
90 IF 2*INT(Z/2) = Z THEN Z = Z + 1
100 H = 3 + INT(RND*2)
110 PRINT "The maximum you can grab is"H
120 GOSUB 320
130 IF E > 0 THEN PRINT "You took"E", and
I took"Q
140 FOR K = 1 TO Z
150 PRINT K;: IF RND >.8 THEN PRINT
160 NEXT K
170 GOSUB 320
180 PRINT "How many will you grab?"
190 E = VAL(INKEY$)
200 IF E<1 OR E>H OR E>Z THEN 190
210 PRINT:PRINT "So you want to grab"E
220 Z = Z - E
230 GOSUB 320
240 IF Z<1 THEN PRINT "You grabbed the las
t one":PRINT ,"so I win!!":END
250 Q = Z - 1 - INT((Z-1)/(H+1))*(H+1) - I
NT(RND*2) + INT(RND*2)
260 IF Q<1 OR Q>H THEN 250
270 GOSUB 320
280 Z = Z - Q
290 IF Z<1 THEN PRINT "I grabbed the last
one":PRINT ,"so you win!!":END
300 GOSUB 320
310 GOTO 110
320 PRINT
330 PRINT "#####"
#*#
340 PRINT
350 FOR O = 1 TO 200:NEXT O
360 RETURN

```

CADDY

Now it's time for you and your versatile computer to tackle the Microchip. Golfcourse, with our next program, CADDY.

You have nine holes to negotiate, and as you'll see as you play the game, the computer obligingly keeps the score card for you. After each hole it will tell you how you are doing to date, and will work out your average score per hole. All you have to do is hit the ball! If you overshoot, the computer will automatically make sure the next shot is back towards the hole.

You'll find it pretty tricky going, especially on holes with a high difficulty factor.

Here's CADDY in action:

```

Score up to this hole is 7
<<< Hole number 2 >>>

```

DIFFICULTY FACTOR IS FOUR

```

o
#####\#####
#####
#####
#####

```

Enter stroke strength? 2

```

You did it!!
#####\#####
#####o#####
#####

```

After that stroke your score is 5
The game so far:
Hole 1 took 7 strokes
Hole 2 took 5 strokes

The average so far is 6

Score up to this hole is 12
<<< Hole number 3 >>>

DIFFICULTY FACTOR IS FOUR

o
#####\ /#####
o #####
^^

Enter stroke strength? 14

o
#####\ /#####
o #####
^^

After that stroke your score is 2

You did it!!

#####\ /#####
o #####
^^

After that stroke your score is 9

The game so far:
Hole 1 took 7 strokes
Hole 2 took 5 strokes
Hole 3 took 9 strokes

The average so far is 7

The score for 3 holes is 21

Enter stroke strength? 5

You did it!!

#####\ /#####
o #####
^^

After that stroke your score is 3

The game so far:
Hole 1 took 7 strokes
Hole 2 took 5 strokes
Hole 3 took 9 strokes
Hole 4 took 9 strokes
Hole 5 took 6 strokes
Hole 6 took 4 strokes
Hole 7 took 7 strokes
Hole 8 took 6 strokes
Hole 9 took 3 strokes

The score for 9 holes is 56

End of that round, golfer!

You scored 56
and your average per hole was 6

Enter 'Y' for another round, or 'N' to quit

OK, thanks for playing, champ

Here's the listing, golf pro:

CAVALCADE OF PUZZLES

There is no need to explain CAVALCADE OF PUZZLES. The rules are all within the program, which presents a series of fun activities and games in a sequence. As you'll discover when you play it, you have to complete one game before you can move on to the next.

The listing is pretty long, but you can convince yourself it is worthwhile by thinking of the peaceful time you'll have once it is in. Whenever a well-meaning friend tells you how wonderful it is that you have a personal computer, and then adds "but what can you do with it?" all you need to do is load this program up, and then go and read a book for an hour or so in peace, while the computer does the job of entertaining.

Here is CAVALCADE OF PUZZLES underway:

Think of a number between
one and sixty-three

I will show you five
screenfulls of numbers.

If your number is on the screen,
just press 'Y' (for 'yes').
if it's not on the screen,
then simply press the 'N'

I'll tell you the number you
thought of at the end of the
game

```
1 3 5 7 9 11 13 15 17
19 21 23 25 27 29 31

32 33 34 35 36 37 38
39 40 41 42 43 44 45
46 47 48 49 50 51 52
53 54 55 56 57 58 59
60 61 62 63

Your number was...

Press 'Y' if your number
is here, 'N' if it is not

N

17 !

I'm going to think of a number
between one and 40 and you
have just six guesses to get
it right...if you do, you
get to play the next game

If you don't get it right,
you'll be given an easier
puzzle to work out...and
so on, until even someone
as stupid as a mere human
could solve it...

Please stand by...

OK, I'm thinking of my
number between one and 40

Enter guess 1

? 20

Too low!

Enter guess 2

? 30

Too high!

Enter guess 3

? 25

Too low!

Enter guess 4

? 26

Wowee!!! Zap!!!

You did it baby...

Now, it's time to
be amazed...

Follow these instructions,
and press RETURN after
you've carried them out...

Start by multiplying your
age by two...
?

Now add five to that...
?

Now multiply that by 50...
?

Now subtract 365 from that...
?

Now add the amount of loose
change in your pocket...
?

Now give me the number
you've ended up with...
? 1402

You have 17 change...

and are 15 years old...

Now to get your mind
back into gear...

In this game, we start
with two sets of four
objects in a line, with
a space between them,
like this:

\$\$\$\$ ****

That was move 9

You have to get them so
they look like this:

**** \$\$\$\$

in the shortest possible
time...

\$ \$ * * \$ \$ * *
1 2 3 4 5 6 7 8 9

You have 3 correct
Which number piece to move?

You can only slide into
empty space, or jump over
one piece into an empty
square....as I'll now
demonstrate...

That brings us to the end
of our cavalcade of puzzles

\$\$\$* \$ *

and so on....

Enter 'Y' to play them again
or 'N' to quit...

Press RETURN when you're
ready to play...
?

Thanks for spending so
much time playing with
me...it sure was fun!

See you again some time...

And here's that long listing I promised you:

ROBOT MINEFIELD

Time now to face the terrors, the dangers, and the horrors of the ROBOT MINEFIELD. There you are, peacefully tripping along one day in the sun, when suddenly you find yourself trapped in a walled area, with a number of manic robots, all bent on your destruction.

The robots are shown on the display as dollar signs, the H is you, and the asterisks (*) are mines which are deadly to both you and robots. Robots, pretty clumsily programmed, can detect you, but they cannot detect mines. Therefore, your salvation lies in getting a mine or two in between you and the robots, so that when they come towards you they'll smash into mines and be wiped out.

The robots have one trick up their sleeves. They can merge into one another, so you may think only one robot is approaching you, when at the last minute it splits into two or more, one going each way around a mine. This is not a game for those who seek the quiet life.

You can move north, south, east or west (with north at the top of the screen), and you enter the move you want to make by entering the initial of the desired direction (so you enter "N" to go north, "S" to go south and so on).

NOUGHTS AND CROSSES

I'm sure that NOUGHTS AND CROSSES needs no introduction. Here is a program which plays fairly well, but not in a totally predictable manner, so you stand a fair chance of winning a few games.

This may not sound like a big deal. However, many NOUGHTS AND CROSSES programs have been written so that a draw is the best you can do, if you are not actually beaten by the machine.

This program decides who will go first in each game, and responds swiftly to your moves. You move just by entering the number of the square into which you want to move.

Let's see NOUGHTS AND CROSSES in action:

Enter your move..	1 2 3	0 X 0	1 2 3	0 X 0
	4 5 6	X X -	4 5 6	- X -
	7 8 9	- 0 X	7 8 9	- - X

Enter your move...	1 2 3	- - -	1 2 3	0 - 0
	4 5 6	- X -	4 5 6	- X -
	7 8 9	- - -	7 8 9	- - X

Enter your move...	1 2 3	- - 0	1 2 3	0 X 0
	4 5 6	- X -	4 5 6	- X -
	7 8 9	- - -	7 8 9	- - X

Enter your move..	1 2 3	- - 0	1 2 3	0 X 0
	4 5 6	- X -	4 5 6	- X -
	7 8 9	- - X	7 8 9	- 0 X

It's a draw!	1 2 3	- - 0	1 2 3	0 X 0
	4 5 6	- X -	4 5 6	- X -
	7 8 9	- - X	7 8 9	- 0 X

I'll have the first move

Enter your move...

```
1 2 3  - - -
4 5 6  - - -
7 8 9  - - -
```

```
1 2 3  - - 0
4 5 6  - 0 -
7 8 9  X X -
```

```
1 2 3  - - -
4 5 6  - 0 -
7 8 9  - - -
```

```
1 2 3  - - 0
4 5 6  - 0 -
7 8 9  X X 0
```

Enter your move...

Enter your move...

```
1 2 3  - - -
4 5 6  - 0 -
7 8 9  - X -
```

```
1 2 3  - - 0
4 5 6  - 0 X
7 8 9  X X 0
```

```
1 2 3  - - 0
4 5 6  - 0 -
7 8 9  - X -
```

```
1 2 3  0 - 0
4 5 6  - 0 X
7 8 9  X X 0
```

I'm the winner!

Here's the program listing:

```

Finally, in this section of the book, we have a slot machine game, LAS VEGAS HIGH. You need only decide how much you'll bet before pulling the handle on the machine (which you do by pressing the spacebar) and the reels will whirl away.

Here's the making of a million (or so):

You have \$ 250

How much do you want to bet? 140

OK, sir, \$ 140 it is!

Press the spacebar to play

```

/.....\
  * {{PLUM}} * << Lemon >> * {{PLUM}} *
>> A PAIR <<

```

And you've won \$ 98 !

So you now have \$ 348 .

You have \$ 348

How much do you want to bet? 172

OK, sir, \$ 172 it is!

Press the spacebar to play

Cherry # << Lemon >> # Bell

A BELL at the end is a bonus!

And you've won \$ 103 !

So you now have \$ 451

Lady Luck has certainly smiled on you!

You have \$ 758

How much do you want to bet? 500

OK, sir, \$ 500 it is!

Press the spacebar to play

```

/*****
 * << Lemon >> * $ Apple $ * # Cherry # *
 *****/

```

And you've lost \$ 500

So you now have \$ 258

Hi there, gambler!

You have \$ 8

How much do you want to bet? 1000000

You ain't got that much!

How much do you want to bet? 8

OK, sir, \$ 8 it is!

Press the spacebar to play

```
/~~~~~\
  * $ Apple $ * << Lemon >> * {{PLUM}} *
```

And you've lost \$ 8

That's the end of the line,
oh once mighty gambler...

You're stone, flat broke!!

Press 'Y' if you'd like to
have another go at breaking
!!!! LAS VEGAS HIGH !!!!
(or press 'N' if you wish to leave)

And this is the way to do it:

```

Fun with your Printer CELESTIA

The first of the two programs in this section is CELESTIA, which you can run either on your TV screen, or on the screen and to the printer at the same time. It produces an infinite series of evolving patterns.

The patterns develop according to the rules of the famous computer game of LIFE, developed by John Conway while at Gonville and Caius College at Cambridge in the UK. Martin Gardiner spread the game throughout the world when he wrote about in Scientific American in October, 1970.

In LIFE, cells are born, grow and die according to rules which Conway invented. Each cell on a grid (the colony of cells is imagined to be evolving on a grid) is surrounded by eight others, and the state of those eight other cells dictates what happens to the cell in question in the following generation.

The rules which govern the evolution of the cells are as follows:

* If a cell has two or three surrounding it, it survives to the next generation

* If there are three, and just three, full cells next to an empty one, a cell will be 'born' in that empty space in the next generation

*Any cell with four of its neighboring cells occupied dies in the next generation

Don't worry, you don't have to know the rules, as the computer interprets them quite happily by

itself. The rules produce patterns which are far more attractive (and far less predictable) than you could possibly imagine by reading the rules. There is just one extra twist in this program, which makes it even more effective. CELESTIA actually prints out four colonies each time a colony evolves. The original colony is in one quadrant of the screen, and the other three quarters of the screen contains reflections of the original one.

CELESTIA is incredibly effective, as you can see:

```

10 REM Celestia
20 GOSUB 450:REM Initialise
30 GOSUB 60:REM Print out
40 GOSUB 280:REM Evolve

296

BILLBOARD, as you can see from the following sample run, takes a message of any length (up to the maximum string length permitted by your system) and turns it into a printed message down the side of your printer paper. The printed letters can then be used to decorate your walls, cut up to form posters, or used however your imagination dictates.

Space Games

Good old space, the final frontier. No collection of computer games would be complete without a few space games. Unfortunately, most games of this type rely on use of a particular computer's graphics set, and on moving graphics. Of course, to make this a game collection which would be 'universal' we couldn't assume access to a particular type of screen. Display file PEEKs and POKEs are among the least transportable aspects of any program.

Therefore, the space games in this collection rely on either just text output, or graphics output of a limited nature (such as using <*> to represent a space ship). Even this apparently limited approach works surprisingly well, and it should not take you long, once you get the programs up and running, to adapt them to take advantage of your particular computer's facilities.

MOONLANDER

I and II

There are two versions of our MOONLANDER program. I suggest you start off with the simpler of the two -- just called Moonlander -- and when you're confident you can land on the moon successfully two times out of three, you can graduate to REALTIME LANDER, which uses INKEY\$ to strobe the keyboard, and demands quick thinking to save your craft from disaster.

The scenario of these programs is pretty familiar. You are landing on the moon, with limited fuel, and for some reason your onboard computer is incapable of doing anything except reporting the state of the flight to you. The information you get is, of necessity, limited but adequate.

You are told, at all times, your height above the moon's surface, how much fuel you have left, and the speed with which you are descending. You have to enter the correct amount of thrust to ensure you land gently on the surface. The fuel you have is limited, so you must ration it to ensure you have enough left in the last few seconds of flight to cushion your impact. A 'high-score' feature (lines 370 and 380) ensures you and your friends return to this program time and time again in an effort to get a better 'galactic rating' and to creating a less deep crater.

Here is MOONLANDER in action:

Height: 674 Velocity: -24
Fuel: 259

<*>

Thrust? 17

Your ship crashed at 106.5 kph
creating a 4792 meter deep crater

Your galactic rating is 6.5

Best rating so far is 6.5

Please stand by for your next mission

This is the listing for the simpler version of the game:

```

10 REM Moonlander
20 HS = - 10000
30 RANDOMIZE VAL(RIGHT$(TIME$,2))
40 A = - 20 - INT(RND*60):REM Initial velocity

HYPERWAR

HYPERWAR is a major space simulation, which puts you in charge of patrolling a cube-shaped sector of space, which is ten parsecs along each side. The enemy is the race known as the Dosznti. There is only one Dosznti ship in this sector, and it is moving slowly through the cube as you play. Although you cannot destroy the ship, you can kill a number of individual Dosznti. In fact, the aim of the game is to get your 'alien kill total' to the highest point possible before your energy banks are exhausted. Although there are many, many more Dosznti in this sector than there are humans, the aliens are notoriously bad shots, so your chance of wiping out a lot before your mission is terminated is rather high.

You can only fire at the Dosznti when you are within three units of their position. Attempting to fire when they are out of range leads only to the crew response 'The Dosznti ship is not within range, sir'.

You have a limited amount of energy, and each successful hit by an alien craft diminishes your energy supply.

I will not explain the game in any more detail, because to do so would diminish the enjoyment you'll get from playing it. The 'behavior of space' does not change from game to game, so you should find you begin to learn the tricks of space warfare after the first game, leading to higher and higher scores as you continue to play it. The game tends to explain the rules to you as you play, and the screen display has been organised to make it as clear as possible what is going on.

Here's a snapshot of HYPERWAR in action:

Status report from master control:

Energy in main and auxiliary banks: 53.75

Stardate timer reads 49

>>>Ships galactic co-ordinates are 10 4 2

>>>>Dosznti mothership located at 10 2 5

The Dosznti is to the west behind us, captain

Brain Games

Brain Games

I guess 90% of all games could, without stretching the definition too much, be called 'brain games'. After all, they demand a certain amount of brain-power and application from you to play.

However, the programs in this section under the heading of BRAIN GAMES are here because they demand a little more intellectual effort than several of the other games in the book.

Here you'll find FASTERMIND where you'll have to deduce a four-digit code invented by your computer, tax your mathematical ability as you solve magic stars in IDAHO STARS and save your precious neck by deducing a word the computer has chosen in EXECUTIONER.

As well, you'll try to unlock a twisted cube in CUBIC, will settle down to a game or two of MUMBLE MARBLE (generally known as a "Solitaire" and named, in this case, because the game in 'real life' uses marbles on a board) and will have to work under the pressure of a relentless clock to locate some atoms within a CYCLOTRON.

If your brain still has any power left after all that, you can attempt a task which may appear impossible in FLIPPER and work out an algorithm to solve the SWITCHEROO problem in the fewest number of moves.

Finally, when your brain has been brought into shape by the exercise of solving all the other problems in this section you can attempt to deduce the map of a cave system in SEARCHING FOR DARYL. Don't expect this one to be easy. Concentration and patience are vital to solve it.

FASTERMIND

We'll start with something fairly simple -- FASTERMIND. You are probably already familiar with this kind of game, in which you have to try and crack a code developed by another player.

In this program, the computer thinks of a four-digit code (using the numbers 1 to 9, and making sure that no digit is repeated within the code) and you have to try and work out what it is within eight goes.

Each guess will get feedback in terms of "blacks" and "whites", where a black is your reward for getting a correct digit in the correct position, and a white is awarded if you have a digit right, but it is not in the right position within the code.

And here's the listing so you can get your brain working with a sixpack or two of FASTERMIND:

```
10 REM Fastermind
20 CLS
30 N = 1
40 PRINT "Press a key"
50 N = N + 1
60 IF INKEY$ = "" THEN 50
70 RANDOMIZE N
80 CLS
90 PRINT "Fastermind"
100 PRINT
110 PRINT "When you are told to do"
120 PRINT "so, enter a 4-digit number"
130 PRINT "and then press RETURN."
140 PRINT
150 PRINT "Digits can be repeated."
160 PRINT
```

```
170 PRINT "You have 8 goes to break"
180 PRINT "the difficult code."
190 FOR Z=1 TO 3000:NEXT Z
200 CLS
210 DIM B(4)

(3);B(4)
670 END
680 PRINT:PRINT:PRINT "Well done, Master
brain!"
690 PRINT
700 PRINT:PRINT "You got the answer in"
710 PRINT TAB(5);"just";C;"goes"

```

IDAHO STARS

IDAHO STARS are stars with a special property -- numbers placed on the cross-over points of the lines forming them will, when added together, produce the same total, no matter which line of numbers is chosen.

Here, for example, is one such star:

As you can see, each line on the star sums to the same total. In this program, the computer generates an IDAHO STAR, leaving two or three of the numbers as zeroes for you to work out as quickly as you can:

Here's the program in action:

0
10 0 10 5
2 5
6
0 20 18
10 11 10 5 This is go number 1
2 5 Enter any number which you
think is part of the star? 11
6
20 18
3

You have 9 right so far

This is go number 2

Enter any number which you
think is part of the star? 3

10 11 10 5
2 5
6
20 18

Yes, you've solved it!

And it only took 2 goes...
Press 'Y' if you'd like to
try another Star of Idaho,
press 'N' to stop.....

0

10 16 13 9
7 9
8
22 0

This is go number 1

Enter any number which you
think is part of the star? 7

10 16 13 9
7 9
8
22 0

You have 8 right so far

This is go number 3

Enter any number which you
think is part of the star? 15

10 16 13 9
7 9
8
22 23

Yes, you've solved it!

And it only took 5 goes...
Press 'Y' if you'd like to
try another Star of Idaho,
press 'N' to stop.....

OK, thanks for playing

This is the listing to produce your own IDAHO STARS (and note you can change the 3 in line 630 to a higher number if you want to produce stars which are more difficult to solve:

```

EXECUTIONER

As you can tell, this game is a computer variation of the old pencil-and-paper game HANGMAN. In this game, the computer chooses a word from its store (held in the DATA statements from 500 to 540) and then challenges you to guess it.

The number of guesses you'll get is related to the length of the word (see lines 120 and 170).

Let's see some hapless human (me) try to work out which word the computer has chosen:

.....

You have 0 correct letters

8 chances left...

.E...

Enter your next guess? E

You have 1 correct letters

8 chances left...

Enter your next guess? T

.E..T

You have 2 correct letters

8 chances left...

Enter your next guess? Y

.E..T

You have 2 correct letters

7 chances left...

Enter your next guess? A ME..T

You have 3 correct letters

2 chances left...

Enter your next guess?

ME.IT

You have 4 correct letters

2 chances left...

Enter your next guess?

MERIT

Whew! You've staved off
execution for another day
You got it in 11 guesses

The Executioner's word was MERIT

This listing will enable you to risk your neck in
the noble cause of increasing your vocabulary:

```
10 REM Executioner
20 CLS
30 N = 0:Y = 0

CUBIST

This is a two-dimensional version of the colored cube puzzle which swept the world from Hungary.

The 'cube' starts off looking like this:

1	1	2	2
1	1	2	2
3	3	4	4
3	3	4	4

After some manipulation by the computer, it will look something like this:

1	2	1	2
3	3	3	2
3	1	4	1
4	2	4	4

Your job is to get it back into its original state in as few moves as possible. The numbers on the cube rotate in groups of four, spinning in a clockwise direction. This means

1 2
3 4 when rotated will look

like this 3 1
4 2

You enter a number in order to rotate the elements of the cube. The key to move is as follows:

2	3	4
6	7	8
10	11	12

Let's look at the effect of a couple of twists on the cube shown on the previous page:

Enter your choice (2 - 12) but not 5 or 9? 6

```
1 2 1 2
3 3 3 2
1 3 4 1
4 2 4 4
```

Your cubist twist number 1

Enter your choice (2 - 12) but not 5 or 9? 6

```
1 2 1 2
1 3 3 2
3 3 4 1
4 2 4 4
```

Your cubist twist number 2

This is the listing for CUBIST:

```
10 REM Cubist
20 DIM A(4),B(16)
30 RANDOMIZE VAL(RIGHT$(TIME$,2))

1
540 IF P <> 2 THEN RETURN
550 PRINT:PRINT "You solved it in just" F -
10 " twists"
560 PRINT:PRINT "Well done, cubist!"

```

MUMBLE MARBLE

Our next brain game is a computer version of the game you probably know as 'Solitaire' in which you have to move marbles around a board. At the start of the game only the center hole is empty. You can jump over marbles into empty holes, and you remove the marble so jumped over. The idea of the game is to end up with just one marble in the center hole.

Many stories have been told about the origin of this game. The most interesting of these tales is the one that says the idea of the game was worked out by a prisoner in solitary confinement in the Bastille, who devised it as a way to relieve the monotony of his imprisonment. Whether that story is true or not, there is no doubt that the game can become quite addictive, as you try to devise a foolproof way to solve it.

Here's what the MUMBLE MARBLE display looks like at the start of the game:

Enter side co-ordinate first
Enter 99 to concede

1	2	3	4	5	6	7	
							1
							2
							3
							4
							5
							6
							7

Moves so far: 0

A few moves later it could look like this:

1	2	3	4	5	6	7	
		0	0	0			1
		0	*	0			2
0	*	0	0	0	0	0	3
0	0	*	0	0	0	0	4
0	0	0	0	0	0	0	5
		*	0	0			6
		*	0	0			7

Moves so far: 4

There are 28 marbles on the board
Which marble do you want to move? 41
41 to where? 43

Here's the listing, so you can set out to solve the problem yourself:

```

10 REM Mumble Marble
20 GOSUB 400
30 GOSUB 250
40 REM ACCEPT MOVE
50 PRINT "Which marble do you want to move";
60 INPUT A
70 IF A = 99 THEN GOTO 240

CYCLOTRON

In CYCLOTRON, you fire atoms into the machine from the top, by specifying a number, and you have to try and locate particles of antimatter hidden within the machine from the behavior of the atom.

If the atom hits a particle of antimatter it will either be absorbed, or deflected to the right or left. An atom may be effected by more than one particle of antimatter which makes the resolution of the problem even more difficult.

There are always three particles of antimatter in the machine, although they could well all be in the same number cyclotron. You have an extremely limited number of goes in order to locate the antimatter. At each go, you can either enter the number where you want to enter an atom, or be reckless and enter 8, which gives you a chance to guess the location of the antimatter particles.

This is what it looks like when it is up and running:

```

You have 6 seconds
Enter cyclotron number,
or 8 if you think you know
where the antimatter lies
? 3

```

3

```

- - - - -
- - - - -
- - - - -
- - - - -
- - - - -

```

3

The atom emerged from 3

You have 5 seconds
 Enter cyclotron number,
 or 8 if you think you know
 where the antimatter lies
 ? 5

```

      5
  - - - - -
  - - - - -
  - - - - -
  - - - - -
  - - - - -
  
```

The atom has been absorbed

You have 2 seconds
 Enter cyclotron number,
 or 8 if you think you know
 where the antimatter lies
 ? 8

Where do you think
 the antimatter lies?
 ? 3,5,4

Well done. You located the
 antimatter with 2 seconds
 to spare

Your best time so far is 4

And here's the listing for your very own cyclotron:

```

10 REM Cyclotron
20 CLS
30 N = 0:HS = 9:DIM B(7),Q(3),W(3)
40 PRINT "Press a key when you're"
50 PRINT "ready to play"

SWITCHEROO

In SWITCHEROO, you are presented with the digits 1 to 9 arranged in a random order, and you have to get them into 123456789 order, in as few moves as possible.

You enter your moves as numbers, and the computer performs a 'switcheroo' using the number you've entered. It works like this:

Please stand by...

7

Move number 1

79

798

798654321

7986

Which number to switcheroo?

79865

798654

Move number 3

7986543

79865432

123456897

Which number to switcheroo?

Move number 4

123456879

Which number to switcheroo?

Move number 6

123456798

Which number to switcheroo?

123456789

You did it, champ!

And it took just 7 moves...

This is the listing for the game:

```
10 REM Switcheroo
20 CLS
30 PRINT:PRINT "Please stand by..."
40 GOSUB 100
50 GOSUB 230
60 IF A$ = "123456789" THEN 400
70 M = M + 1
80 GOTO 50
90 END
100 RANDOMIZE VAL(RIGHT$(TIME$,2))
110 M = 1:X = 0
120 A$ = ""
130 FOR T = 1 TO 9
140 L = INT(RND*9) + 49
150 Q = 1
160 IF MID$(A$,Q,1) = CHR$(L) THEN 140
170 IF Q<T THEN Q = Q + 1:GOTO 160
180 A$ = A$ + CHR$(L)
190 PRINT A$
```

```
200 PRINT
210 NEXT T
220 RETURN
230 REM Print out
240 CLS

380 A$ = LEFT$(A$,R-1) + B$
390 RETURN
400 PRINT:PRINT:PRINT
410 PRINT A$
420 PRINT:PRINT:PRINT
430 PRINT "You did it, champ!"
440 PRINT:PRINT "And it took just"M"moves..
."
450 END
```

FLIPPER

This intriguing game can provide you with a considerable degree of mental stretching. When you run the game, you'll see a mix of X's and *'s on a three by three grid. You have to end up with an X in the middle, and eight *'s surrounding it.

You enter the number of the place you want to hit with your flipper. Flipping a corner piece causes those adjoining it to change into their opposites (that is an X becomes an *, and an * becomes an X). Hitting the middle piece on a side with your flipper causes the two on either side of it to change, and hitting the middle piece changes the middle pieces on each of the sides.

The piece you hit always changes in each case.

Here's what it looks like in action:

You flipped 5

1	2	3	X	X	X
4	5	6	*	X	*
7	8	9	*	X	*

That was move 1

Number of X is 5

You only need one - in the middle square

Which one do you want to flip?

You flipped 9

1	2	3	X	X	X
4	5	6	*	*	X
7	8	9	*	*	X

That was move 2

Number of X is 5

You only need one - in the middle square

Which one do you want to flip?

You flipped 4

1	2	3	*	X	X
4	5	6	X	*	X
7	8	9	X	*	X

That was move 3

Number of X is 6

You only need one - in the middle square

Which one do you want to flip?

You flipped 1

1 2 3 X * X

4 5 6 * X X

7 8 9 X * X

That was move 4

Number of X is 6

You only need one - in the middle square

Which one do you want to flip?

This is what you're aiming for:

You flipped 5

1 2 3 * * *

4 5 6 * X *

7 8 9 * * *

You solved it in just 22 moves

Here's the listing so you can
do it yourself:

```
10 REM FLIPPER

SEARCHING FOR DARYL

Finally, we have the most troubling program of all. Daryl is lost in an underground cave system of the most perplexing complexity.

You have to enter the system, and work your way to Daryl who is in cave 29, and then get out again.

The caves are connected by a stable, coherent set of tunnels, and you should try and solve this puzzle by making a map as you work out how the caves link up. Be warned that some tunnels travel underneath other ones. The caves are not laid out in neat numerical order. Rather, the cave numbers are provided just so you can refer to them easily.

You may find the problem difficult, but it is by no means impossible. The references within the program to directions (such as N for north and so on) should be examined with care. In fact, north is not up in the case, nor is south down. Rather, they refer to directions as if the entire cave system was being viewed from above, and the direction at the top of the system was the north, the east was the right hand side and so on. Anyway, the direction clues are more likely than not to confuse you when you first try this program.

Don't give up easily. It can be done. The number of possible routes is extraordinarily high, so once you've solved it one way, you may like to work out another way of getting through the system. Veterans of the program like to get to Daryl by a new route each time they run it, and then return to the entrance (carrying Daryl) by a completely different route.

To prove the problem can be solved, here is one route to Daryl, with another one getting out of the system:

You are on your way to find
Daryl, trapped in this cave system

You are in cave 1

Tunnels lead from this cave to:

2 7 10

Creating your own Games

You may well find, after you've been programming for some time, that although you've got many of the skills you need to write games of your own, you're a little short on ideas. If that's the case, you should find this section of the book of interest to you. I'm going to outline a number of games which seem to me to be ideal for conversion to computer games.

A second book of computer games programs is now in preparation, and I'm looking for new programs to include in that volume. If you've written any games which you think would be suitable (that is, they are worthwhile, original programs, and are not machine-dependant) I'd very much like to see them, with a view to purchasing them to use in the next volume. You'll be given full credit for the program, of course. Only printed listings, dumped direct from the computer, can be considered. Write to me care of the publisher.

The reason I've mentioned that at this point is that I'm quite willing to consider programs based on ideas given in this section of the book, or programs which are based entirely on your own ideas.

Let's get back now to writing your own games. Unless you're converting a well-known game, such as Checkers, when your program will be expected to coincide in every respect with the non-computer version, you do not need to ensure that your computer developments of these ideas slavishly follows the outlines here. You'll probably find that, after a certain degree of development, the game takes off on its own, and may well end up in due course bearing little resemblance to its 'parent'. This is all to the good.

GAMES TO ADAPT

SHUFFLEBOARD: Players slide flat, circular pieces along a board towards a triangular 'target' which contains painted circles with numbers on them. A piece ending up entirely within the numbered circle gives the player the score of that number. There are many possible variations of this, including darts-like target games. Once you get a shuffleboard program running, you may well find that only cosmetic changes are needed to convert it into a ten-pin bowling game.

HORSESHOE: Starting with a board like this, with one player's pieces at the positions marked A, and one at those marked B, the players take it in turns to move along a line to a vacant spot:

The game ends when a player discovers he or she (or it) cannot move. Despite its simplicity, this is an interesting game, as you'll discover when you play it.

DAMOCLES: This game is like HORSESHOE, but uses a larger board, and three pieces per player. The aim of the game is the same as HORSESHOE, and uses this board:

MU-TORERE: This game, which originated among the Maoris in New Zealand, is played on a board shaped like an eight-pointed star, with each point of the star joined to a circle in the middle. This circle

is called the putahi. The players start with four pieces each, which are placed on the outside points, with all of one player's pieces occupying points next to each other. The aim of the game, as in the last two we've discussed, is to make it impossible for a player to move. You can move from one point to an adjacent empty point, or from the putahi to any vacant point. The third possible move is from a point to the putahi, but this move can only be made if at least one of the points immediately adjacent to the one from which you intend to move is occupied by an opponent's piece.

BINGO: This game is usually played with cards marked with numbers, which are crossed off as numbers are drawn at random from a pool, the winner being the player who first crosses off five in a row on their card, in any direction. It can be greatly simplified for computer use, with the computer generating two 'cards' at random, using numbers from zero to 99, and printing them on a five by five grid. The computer can then choose numbers at random from zero to 99, and do the crossings off, and look for possible wins. The program can be made more interesting to look at by, instead of just generating a random number, including two 'dials' with spinning arrows. The first dial, the 'tens' is marked from zero to nine, and this is spun first. The second dial is marked the same as the first one, except that it represents the 'ones'.

DICE GAMES: As I said in the notes regarding the dice games in the dice section of this book, you should find dice games relatively easy to program on your computer, especially if the computer is not expected to exhibit too much intelligence when playing. There are a number of dice games which you may wish to try and adapt for computer play, including:

DROP DEAD: You need five dice for this. The dice are thrown by the first player, and any which show two or five are removed. The total of the rest is written down, and the dice which fell with a two or

a five are thrown again. After this throw, the dice landing two and five are removed, and the total of the remaining dice is added to the total from the first throw. This process continues until there are no dice left, at which point that particular player's move ends. It is then player two's go, and the same procedure is followed. The winner is the player with the biggest total after both have had their throws. You can make the game the best of, say, three rounds, or limit the total number of throws any player can have per go, regardless of how many dice he or she has left.

MARTINETTI: You need three dice for this, and a score sheet marked with a row of boxes marked from one to 12, and two tokens, one each for you and the computer. You are aiming to traverse the numbers in order, before your opponent manages to do so. Each player takes it in turn to throw the dice. If the throw contains a one, the player's token can be placed in the one square. If the first throw also contained a two, the token could be moved into the two. After box one, players can either take the pip shown on an individual die for a move, or can add together the pips showing to get a desired number. A variation of this game (often called EVEREST) is to 'climb down' through the numbers, after one through to 12 has been achieved. The winner of EVEREST is the first player getting back to base camp on one.

INDIAN DICE: This game is similar to POKER DICE and is played with five dice. The aim is simply to get the best possible 'poker hands'. There is no provision for getting additional 'cards' in one deal. You throw the five dice at once, and that is your hand. The ranking of the hands is as follows (with six highest and ones wild):

- five of a kind
- four of a kind
- full house (three of a kind plus a pair)
- two pairs
- one pair
- highest die

BIDOU: This game is also similar to POKER DICE, however, you aim to get rid of all your chips, rather than win them. The winner of the game is, paradoxically, the person who has lost the most rounds. You need three dice for this game, and a supply of chips which are distributed equally between the two players. A bet is made, and matched, before the players take it in turns to throw the three dice. The throws are ranked as follows, with 'winning throws' coming first:

2 1 1; 2 2 1; 4 2 1; 6 6 6; 5 5 5; 4 4 4;
 3 3 3; 2 2 2; 1 1 1; 3 3 6; 3 3 5; 3 3 4;
 3 3 2; 3 3 1; 1 1 6; 1 1 5; 1 1 4; 1 1 3;
 3 2 1; 4 3 2; 5 4 3; 6 5 4

If the combination thrown is not in the list, the pips are added, with the highest total winning.

BARBOOTH: Also known as BARBUDI, this game is played with two dice, and features winning and losing throws. It is suggested you start with a bank of 30 chips, and give both players a starting stake of 15 chips each, charging two chips per player per round. The players take it in turns to throw the dice. Winning throws are 3 3; 5 5; 6 5; and 6 6. Losing throws are 1 1; 2 2; 2 1 and 4 4. If the players both get winning throws, the one closest to the start of the list wins (that is, 3 3 is better than 6 6). If both throw the same winning throw, the bank gets the money. If one player throws a combination which is not a winning one nor a losing one, and the other throws a losing throw, the loser's chips go into the bank, and the other player retains his or her chips.

If one player throws a winning throw, and the other a non-ranking combination, the winner gets his own chips back, as well as those bet by the loser. If, however, one player throws a winning combination,

and the other a losing combination, the bank contributes the same number of chips as have been bet in total. The game continues until either player, or the bank, runs out of chips. The player holding the maximum number of chips at this point wins. Note that this way of distributing the wins and losses is not the same as BARBOOTH when played as a 'professional' gambling game, but is a pay-off scheme which is relatively easy to computerise, and makes for an interesting game.

FIVE THOUSAND: There are no prizes for guessing that the first player to score over 5000 points in this game is the winner. Played with as many players as you like, all you'll need in the way of game equipment is five six-sided dice. Each player takes it in turn to throw the five dice, and scoring is carried out in the following way:

- a 5 is worth 100
- a 2 is worth 50
- three 5's thrown in one go are worth 1000
- three 2's thrown in a go score 500
- three of a kind (apart from 2's and 5's. are worth 100 times their value (that is three 1's are worth 100 points, and three 6's are worth 600
- if the sequence 1, 2, 3, 4 and 5 is thrown in a single go, this scores 1500
- 2, 3, 4, 5 and 6 in one throw are worth 2000 points

Note that 4's and 6's do not score in this game, except as part of a sequence. Once you've thrown, you can -- if you like -- throw the non-scoring dice again. However, if the next throw gains no score, the turn ends, and the overall score for the throw is zero. So long as a scoring throw has been made, any dice 'left over' can be thrown.

The game rewards the slow and careful player with a reasonable score, but gives him or her no chance against a player who decides to take a chance and tries to get a massive score in a single throw.

CARD GAMES: Once you've worked out a routine to get the computer hold, shuffle and deal the cards (and such a routine is in my version of Concentration in this book) you have the raw bones of a host of games. Any book of card games will give you more ideas than you can possibly cope with. Here are a few to start you off:

TRENTE AND QUARANTE: This game, which originated in 17th century Europe, is also known as ROUGE ET NOIR. Six decks of cards are used in the casino version, but it works well with a single deck. The cards are dealt into two rows, with the total of each row being examined after each row has had an additional card. Court cards (jack, queen, king) count as ten, with all other cards (including the ace) counting as their face value. The moment the total of a row equals or exceeds 31, no more cards are added to that row. However, the dealer keeps adding to the other row until it, too, equals or exceeds 31. The first row is called 'black', regardless of the suite of the cards involved, and the second row is 'red'.

You can bet that, at the end, the red row or the black row total will be closer to 31. You can also bet that the color of the first card to be dealt will match the color name of the winning row. All bets are made against the bank, and winners receive their bet back, plus that amount again (odds of one to one). If both rows equal 31, the bank takes half the stake and returns the rest to the player.

CARD CRAPS: This game was devised to get around laws passed by some US States which outlawed craps played with dice. You use a special deck of 48 cards, made up from the aces, 2's, 3's, 4's, 5's and 6's, from two decks of cards. The game follows the standard rules of craps (which are similar to those used in the game SEVEN/ELEVEN in this book).

In its simplified form, without the somewhat complex betting combinations, you play as follows:

- a total of 2, 3 or 12 is 'craps' and the dealer loses, passing the cards to the next player to deal

- a total of 7 or 11 is a 'natura' and the dealer wins

- any other number (4, 5, 6, 8, 9 or 10) is the player's 'point' and he or she must continue dealing in pairs until the point is dealt again, at which point the dealer wins. However if a 7 is dealt before the point is obtained, the dealer loses

THREE CARD BRAG: This game was the forerunner of poker, and as its name suggests, it is played with hands of three, rather than five, cards. Here are the winning combinations, ranked from highest to lowest:

- 'pryle', three of a kind
- 'on a bike', three in sequence from the same suit
- 'run', three cards in sequence
- 'flush', three cards from the same suit
- 'pair', two of a kind
- 'high card'

A normal deck is used, and aces rank high, except for 'on a bike' and 'run', when 3, 2, ace beats ace, king, queen. You can vary the game by making it SEVEN CARD BRAG, in which the players split their seven cards into two three-card hands of their choice, or NINE CARD BRAG, when three cards are created.

ACE-DEUCE-JACK: This is a simple game, heavily loaded in the dealer's favor, in which players bet on the likelihood that the next card which appears will be an ace, a two (a 'deuce') or a jack.

PUT AND TAKE: This gambling game uses an eight-sided top, which is spun. The game begins with all players having 10 chips, with 30 in the pot. The players take it in turn to spin the top, and -- obeying the instructions which come up on the top -- put chips into the pot, or take them out. A player is out when he or she runs out of chips, and the game ends when the pot is empty. The instructions written on the sides of the top are:

- PUT ONE
- TAKE ONE
- PUT THREE
- TAKE THREE
- PUT FOUR
- TAKE FOUR
- PUT ALL
- TAKE ALL

BOULE: This is a simplified form of roulette which appeared in the 18th century. It is often found in European casinos. The wheel is divided into 18 segments, numbered from one to nine...twice. You can bet on the winning number, whether it will be a red or a black number, even or odd, high or low. Except for the fives on the wheel, which are usually yellow, the reds and blacks alternate, so that there is, for example, a red six and a black six, a red nine and a black nine, and so on. A 'high' number is above five, while 'low' numbers are below it. If you bet successfully on a single number, you'll be paid at seven to one, with a one to one return on the 'characteristic' of a number (such as it being 'high' or 'odd').

BOOKS TO READ

As you've probably gathered by reading through this book, I make a point of reading any book on games I can get my hand on. It doesn't matter whether the book is about computer games or the old-fashioned 'play against another human' type. So long as it is a book of games, I want to see it.

Games books are superb as idea-starters. Read about a game and you've got the seed of a program. And it doesn't matter if the program doesn't end up playing precisely the game you read about. Many great computer games started their lives as an attempt to computerise a more traditional game, and somehow got side-tracked.

I hope some of the following list of books prove as valuable to you as they have to me.

*DISCOVERING OLD BOARD GAMES - R C Bell (Shire Publications, Aylesbury, UK, 1980)

*DISCOVERING DICE AND DOMINOES - R C Bell (Shire Publications, Aylesbury, UK, 1980)

*DICE GAMES NEW AND OLD - William E Tredd (The Oleander Press, London and New York, 1981)

*GAME PLAYING WITH BASIC - Donald D Spencer (Hayden Book Co., Inc., Rochelle Park, New Jersey, 1977)

*GAMES ANCIENT AND ORIENTAL AND HOW TO PLAY THEM - Edward Falkener (Dover Publications, Inc., New York, 1961 - a reprint of an original work published by Longmans, Green and Co. in 1892)

*BASIC COMPUTER GAMES - Ed. David H Ahl (Creative Computing Press, Morristown, New Jersey, 1978)

*MORE BASIC COMPUTER GAMES - Ed. David H Ahl (Creative Computing Press, Morristown, New Jersey, 1979)

*26 BASIC PROGRAMS FOR YOUR MICRO - Derrick Daines (Newnes Technical Books, Butterworths & Co., London and Boston, 1982)

*TABLE GAMES OF GEORGIAN AND VICTORIAN DAYS - F R B Whitehouse (Priory Press, Royston, Herts., UK, 1971)

*PET FUN AND GAMES - Ron Jeffries and Glen Fisher (Osborne/McGraw-Hill, Berkeley, California, 1981)

*COMPUTER GAMES FOR BUSINESSES, SCHOOLS AND HOMES - J Victor Nahigian and William S Hodges (Winthrop Publishers, Inc., Cambridge, Massachusetts, 1979)

*GAMES YOU MAKE AND PLAY - Pia Hsiao, Neil Lorimer and Nick Williams (Macdonald and Jane's, London, 1975)

*WHAT TO DO AFTER YOU HIT RETURN - People's Computer Company (Hayden Book Co., Inc., Rochelle Park, New Jersey, 1980)

*EVERYMAN'S INDOOR GAMES - Gyles Brandreth (Dent, Everyman's Library, London, Melbourne and Toronto, 1982)

*GAMES FOR TWO - John Wasley (Proteus, London and New York, 1981)

*THE ADDISON-WESLEY BOOK OF APPLE COMPUTER SOFTWARE 1982 - Jeffrey Stanton and John Dickey, editors (The Book Company, Lawndale, California, 1982)

*DICING WITH DRAGONS - Ian Livingstone (Routledge & Kegan Paul, London, Melbourne and Henley, 1982)

*FANTASY ROLE PLAYING GAMES - J Eric Holmes (Hippocrene Books Inc., New York, 1981)

Computer Chess books from Computer Science Press:

- * CHESS AND COMPUTERS - David Levy (1976)
 - * MORE CHESS AND COMPUTERS - David Levy and Monroe Newborn (1980)
 - * ALL ABOUT CHESS AND COMPUTERS - David Levy and Monroe Newborn (1983)
- (Computer Science Press, Rockville, Maryland)

GLOSSARY

Accumulator - part of the computer's logic unit which stores the intermediate results of computations

Address - a number which refers to a location, generally in the computer's memory, where information is stored

Algorithm - the sequence of steps used to solve a problem

Alphanumeric - generally used to describe a keyboard, and signifying that the keyboard has alphabetical and numerical keys. A numeric keypad, by contrast, only has keys for the digits one to nine

APL - this stands for Automatic Programming Language, a language developed by Iverson in the early 1960s, which supports a large set of operators and data structures. It uses a non-standard set of characters

Application software - these are programs which are tailored for a specific task, such as word processing, or to handle mailing lists

ASCII - stands for American Standard Code for Information Exchange. This is an almost universal code for letters, numbers and symbols

Assembler - this is a program which converts another program written in an assembly language (which is a computer program in which a single instruction, such as ADD, converts into a single instruction for the computer) into the language the computer uses directly

BASIC - stands for Beginner's All-purpose Symbolic Instruction Code, the most common language used on

microcomputers. It is easy to learn, with many of its statements being very close to English

Batch - a group of transactions which are to be processed by a computer in one lot, without interruption by an operator

Baud - a measure of the speed of transfer of data. It generally stands for the number of bits (discreet units of information) per second

Benchmark - a test which is used to measure some aspect of the performance of a computer, which can be compared to the result of running a similar test on a different computer

Binary - a system of counting in which there are only two symbols, 0 and 1 (as opposed to the ordinary decimal system, in which there are ten symbols, 0, 1, 2, 3, 4, 5, 6, 7, 8 and 9). Your computer 'thinks' in binary

Boolean Algebra - the algebra of decision-making and logic, developed by English mathematician George Boole, and at the heart of your computer's ability to make decisions

Bootstrap - a program, run into the computer when it is first turned on, which puts the computer into the state where it can accept and understand other programs

Buffer - a storage mechanism which holds input from a device such as keyboard, then releases it at a rate which the computer dictates

Bug - an error in a program

Bus - a group of electrical connections used to link a computer with an ancillary device, or another computer

Byte - the smallest group of bits (see bit) which

makes up a computer word. Generally a computer is described as being 'eight bit' or '16 bit', meaning the word consists of a combination of eight or sixteen zeros or ones

Central Processing Unit (CPU) - the heart of the computer, where arithmetic, logic and control functions are carried out

Character code - the number in ASCII (see ASCII) which refers to a particular symbol, such as 32 for a space and 65 for the letter 'A'

COBOL - stands for Common Business Orientated Language, a standard programming language, close to English, which is used primarily for business

Compiler - a program which translates a program written in a high level (human-like) language into a machine language which the computer understands directly

Concatenate - to add (adding two strings together is known as 'concatenation')

CP/M - stands for Control Program/Microcomputer, an almost universal disk operating system developed and marketed by Digital Research, Pacific Grove, California

Data - a general term for information processed by a computer

Database - a collection of data, organised to permit rapid access by computer

Debug - to remove bugs (errors) from a program

Disk - a magnetic storage medium (further described as a 'hard disk', 'floppy disk' or even 'floppy') used to store computer information and programs. The disks resemble, to a limited extent, 45 rpm sound records, and are generally eight, five and a quar-

ter, or three inches in diameter. Smaller 'micro-disks' are also available for some systems

Documentation - the written instructions and explanations which accompany a program

DOS - stands for Disk Operating System (and generally pronounced 'doss'), the versatile program which allows a computer to control a disk system

Dot-matrix printer - a printer which forms the letters and symbols by a collection of dots, usually on an eight by eight, or seven by five, grid

Double-density - adjective used to describe disks when recorded using a special technique which, as the name suggests, doubles the amount of storage the disk can provide

Dynamic memory - computer memory which requires constant recharging to retain its contents

EPROM - stands for Erasable Programmable Read Only Memory, a device which contains computer information in a semi-permanent form, demanding sustained exposure to ultra-violet light to erase its contents

Error messages - information from the computer to the user, sometimes consisting only of numbers or a few letters, but generally of a phrase (such as 'Out of memory') which points out a programming or operational error which has caused the computer to halt program executions

Field - A collection of characters which form a distinct group, such as an indentifying code, a name or a date; a field is generally part of a record

File - A group of related records which are processed together, such as an inventory file or a student file

Hardware - the solid parts of the computer (see 'software' and 'firmware')

Hexadecimal - a counting system much beloved by machine code programmers because it is closely related to the number storage methods used by computers, based on the number 16 as opposed to our 'ordinary' number system which is based on 10)

Hex pad - a keyboard, somewhat like a calculator, which is used for direct entry of hexadecimal numbers

High-level languages - programming languages which are close to English. Low-level languages are closer to those which the computer understands. Because high-level languages have to be compiled into a form which the computer can understand before they are processed, high-level languages run more slowly than do their low-level counterparts

Input - any information which is fed into a program during execution

I/O - stands for Input/Output port, a device the computer uses to communicate with the outside world

Instruction - an element of programming code, which tells the computer to carry out a specific task. An instruction in assembler language, for example, is ADD which (as you've probably guessed) tells the computer to carry out an addition

Interpreter - converts the high-level ('human-understandable') program into a form which the computer can understand

Joystick - an analogue device which feeds signal into a computer which is related to the position which the joystick is occupying; generally used in games programs

Firmware - The solid components of a computer system are often called the 'hardware', the programs, in machine-readable form on disk or cassette, are called the 'software', and programs which are hard-wired into a circuit, are called 'firmware'. Firmware can be altered, to a limited extent, by software in some circumstances

Flag - this is an indicator within a program, with the 'state of the flag' (i.e. the value it holds) giving information regarding a particular condition

Floppy disk - see disk

Flowchart - a written layout of program structure and flow, using various shapes, such as a rectangle with sloping sides for a computer action, and a diamond for a computer decision, is called a flow chart. A flowchart is generally written before any lines of program are entered into the computer

FORTRAN - a high level computer language, generally used for scientific work (from FORMula TRANslation)

Gate - a computer 'component' which makes decisions, allowing the circuit to flow in one direction or another, depending on the conditions to be satisfied

GIGO - acronym for 'Garbage In Garbage Out', suggesting that if rubbish or wrong data is fed into a computer, the result of its processing of such data (the output) must also be rubbish

Global - a set of conditions which effects the entire program is called 'global', as opposed to 'local'

Hard copy - information dumped to paper by a printer

Kilobyte - the unit of language measurement; one kilobyte (generally abbreviated as K) equals 1024 bits (see bit)

Line printer - a printer which prints a complete line of characters at one time

Low-level language - a language which is close to that used within the computer (see high-level language)

Machine language - the step below a low-level language; the language which the computer understands directly

Mainframe - the term for 'giant' computers such as the IBM 307. Computers are also classed as mini-computer and microcomputer (such as the computer you own)

Memory - the device or devices used by a computer to hold information and programs being currently processed, and for the instruction set fixed within a computer which tells it how to carry out the demands of the program. There are basically two types of memory (see RAM and ROM)

Microprocessor - the 'chip' which lies at the heart of your computer. This does the 'thinking'

Modem - stands for MODulator/DEModulator, and is a device which allows one computer to communicate with another via the telephone

Monitor - (a) a dedicated television-screen for use as a computer display unit, contains no tuning apparatus; (b) the information within a computer which enables it to understand and execute program instructions

Motherboard - a unit, generally external, which has slots to allow additional 'boards' (circuits) to be plugged into the computer to provide facilities (such as high-resolution graphics, or 'robot control') which are not provided with the standard machine

Mouse - a control unit, slightly smaller than a box

of cigarettes, which is rolled over the desk, moving an on-screen cursor in parallel to select options and make decisions within a program. 'Mouses' work either by sensing the action of their wheels, or by reading a grid pattern on the surface upon which they are moved

Network - a group of computers working in tandem

Numeric pad - a device primarily for entering numeric information into a computer, similar to a calculator

Octal - a numbering system based on eight (using the digits 0, 1, 2, 3, 4, 5, 6 and 7)

On-line - device which is under the direct control of the computer

Operating system - this is the 'big boss' program or series of programs within the computer which controls the computer's operation, doing such things as calling up routines when they are needed and assigning priorities

Output - any data produced by the computer while it is processing, whether this data is displayed on the screen or dumped to the printer, or is used internally

Pascal - a high level language, developed in the late 1960s by Niklaus Wirth, which encourages disciplined, structured programming

Port - an output or input 'hole' in the computer, through which data is transferred

Program - the series of instructions which the computer follows to carry out a predetermined task

PILOT - a high level language, generally used to develop computer programs for education

RAM - stands for Random Access Memory, and is the memory on board the computer which holds the current program. The contents of RAM can be changed, while the contents of ROM (Read Only Memory) cannot be changed under software control

Real-time - when a computer event is progressing in line with time in the 'real world', the event is said to be occurring in real time. An example would be a program which showed the development of a colony of bacteria which developed at the same rate that such a real colony would develop. Many games, which require reactions in real time, have been developed. Most 'arcade action' programs occur in real time

Refresh - The contents of dynamic memories (see memory) must receive periodic bursts of power in order for them to maintain their contents. The signal which 'reminds' the memory of its contents is called the refresh signal

Register - a location in computer memory which holds data

Reset - a signal which returns the computer to the point it was in when first turned on

ROM - see RAM

RS-232 - a standard serial interface (defined by the Electronic Industries Association) which connects a modem and associated terminal equipment to a computer

S-100 bus - this is also a standard interface (see RS-232) made up of 100 parallel common communication lines which are used to connect circuit boards within micro-computers

SNOBOL - a high level language, developed by Bell Laboratories, which uses pattern recognition and string manipulation

Software - the program which the computer follows (see firmware)

Stack - the end point of a series of events which are accessed on a last in, first out basis

Subroutine - a block of code, or program, which is called up a number of times within another program

Syntax - as in human languages, the syntax is the structure rules which govern the use of a computer language

Systems software - sections of code which carry out administrative tasks, or assist with the writing of other programs, but which are not actually used to carry out the computer's final task

Thermal printer - a device which prints the output from the computer on heat-sensitive paper. Although thermal printers are quieter than other printers, the output is not always easy to read, nor is the used paper easy to store

Time-sharing - this term is used to refer to a large number of users, on independent terminals, making use of a single computer, which divides its time between the users in such a way that each of them appears to have the 'full attention' of the computer

Turnkey system - a computer system (generally for business use) which is ready to run when delivered, needing only the 'turn of a key' to get it working

Volatile memory - a memory device which loses its contents when the power supply is cut off (see memory, refresh, ROM and RAM)

Word processor - a dedicated computer (or a computer operating a word processing program) which gives access to an 'intelligent typewriter' with a large range of correction and adjustment features

More than 40 magnificent games for your computer are brought together in this bumper volume by one of the world's bestselling computer authors. Every kind of game is included for your entertainment:

BOARD GAMES – Chess, Gomoku, Awari, Knightsbridge, Shogun and others

ADVENTURE GAMES – Stronghold of the Dwarven Lords, The Duke of Dragonfear, The Bannochburn Legacy

SIMULATIONS – including Mistress of Xenophobia

DICE GAMES – Chemin de Computer, No Sweat, Under 'n' Over and three more

ARTIFICIAL INTELLIGENCE – including Eliza and Electronic Brain

JUST FOR FUN – Inner Spring, Robot Minefield and five others

FUN WITH YOUR PRINTER – Celestia and Billboard

SPACE GAMES including Moonlander

BRAIN GAMES Fastermind, Switcheroo and several others

Plus how to create your own exciting games, and a chapter of games and program ideas for you to convert.
